Most established safety methods have been developed on the assumption that systems are tractable. As this assumption is no longer universally valid, it is necessary to develop methods to deal with intractable systems and irregular work environments. One way of doing that is to focus on which functions are required to achieve a goal and how they are organized relative to the current situation (e.g., existing resources and demands). This can be seen as a natural continuation of the development that has taken us from sequential task analysis via hierarchical task analysis to functional dependency and goals–means analysis. Doing so will have a major impact not only on how work situations are studied and analyzed but also on how the efficiency and safety of work can be ensured.

## 1  MEANING AND IMPACT OF WORK

Work has been and still is an object of study in many scientific disciplines. Work science, pedagogy, jurisprudence, industrial engineering, and psychology—to name just a few—have all made significant contributions to this field. Therefore, today there is a wide variety of perspectives on work and the corresponding perceptions of human beings.

As an introduction, perhaps a look into another philosophical tradition is necessary—a tradition that is not likely to be accused of offering merely a one-sided and reduced view (Luczak and Rohmert, 1985). The authors of the *Encyclica Laborem Exercens* (Pope John Paul II, 1981) regard work as a positive human good because through work people not only reshape nature to fit their needs but also fulfill themselves in a spiritual sense. They become more human and thus realize creation's divine mandate. According to Luczak and Rohmert, the uniqueness of this definition lies in its ability to stand for itself in every work-related scientific discipline.

The term *work* has always been associated with aspects of burden as well as with those of pride. In history, priority was once given to the first aspect, at other times to the latter (Schmale, 1983). In ancient times work was avoided by people who could afford

it; in contrast, Christianity looked upon work as a task intended by God and elevated successful working within the scope of the *Protestant work ethic* to the standard of salvation, a perception that has often been made responsible for the development of the great advances made during the Industrial Revolution (Weber, 1904/1905).

In connection with the population's attitude toward work, a shift from material to postmaterial values (Inglehart, 1977, 1989) appeared. This silent revolution consists of a slow change from industrial society's appreciation of safety and security to postmaterial society's emphasis on personal liberty. According to Inglehart, this trend is explained largely by development of the welfare state and improvements in education. Inglehart's theory of the silent revolution played an important role in shaping the perception of changing values. Not only the value that has been assigned to work during the various historical eras but also the concept of work itself is different, depending on the ideas of society and humankind as a whole (Hoyos, 1974; Schmale, 1983; Frei and Udris, 1990).

Waged work fulfills, in addition to the assurance of income, a series of psychosocial functions. Research, especially the work on effects of unemployment, indicates the high mental and social benefits of work.

The most important functions are as follows (Jahoda, 1983; Warr, 1984):

1.  *Activity and Competence*. The activity resulting from work is an important precondition for the development of skills. While accomplishing work tasks one acquires skills and knowledge and at the same time the cognition of skills and knowledge (i.e., a sense of competency).

2.  *Structure*. Work structures the daily, weekly, and yearly cycle as well as whole life planning. This is reflected by the fact that many terms referring to time, such as *leisure, vacation*, and *pension*, are definable only in relation to work.

3.  *Cooperation and Contact*. Most professional tasks can be executed only in collaboration with others. This forms an important basis for the development of cooperative skills and creates an essential social field of contact.

4.  *Social Appreciation*. One's own efforts, as well as cooperation with others, lead to social appreciation that in turn produces the feeling of making a useful contribution to society.

5.  *Identity*. The professional role and the task, as well as the experience of possessing the necessary skills and knowledge to master a certain job, serve as a fundamental basis for the development of identity and self-esteem.

How important these functions are is often observed when people lose their jobs or have not yet had the chance to gain working experience. But also in the definition of work by employees themselves, these functions become evident. Despite some contrary claims, work still takes a central position in the lives of many people (Ruiz Quintanilla, 1984). At the same time, distinctions can be observed. Ranking work first does not remain unquestioned any more: Values have become more pluralistic, life concepts more flexible. The number of persons that are not work oriented is increasing; this shows a flexible attitude and is especially the case for younger people (Udris, 1979a,b). This should not be misjudged as a devaluation of work as a sphere of life and least of all as a disappearance of the Protestant work ethic. Young people today differ in several respects from the generation of their parents, which is clearly motivated by the values of an industrial society. Young people have been shaped by the global communication society in which they now live. There is a shift away from values such as obedience or pure fulfillment of duty to values that favor the assertion of needs for self-development and fulfillment (Klages, 1983).

The aspects of work that people consider as most important can be summarized with the help of five keywords. Such listings (e.g., Kaufmann et al., 1982; Hacker, 1986) vary in detail and their degree of differentiation. Essentially, however, they are very much alike:

1.  *Content of work*: completeness of tasks, diversity, interesting tasks, possibility to employ one's knowledge and skills, possibility to learn something new, possibility to take decisions

2.  *Working conditions*: time (duration and position), stress factors (noise, heat, etc.); adequacy of furniture, tools, and spatial circumstances, demanding working speed

3.  *Organizational environment*: job security, promotion prospects, possibilities of further education, information management of the organization

4.  *Social conditions*: opportunities for contact, relations to co-workers and superiors, working atmosphere

5.  *Financial conditions*: wage, social benefits

However, opinions about the weighting of these aspects vary more fundamentally. Schools of work and organizational psychology often differ in the significance they attribute to the various characteristics (Neuberger, 1989). Taylor (1911) gives priority to the economic motive, whereas the human relations movement emphasizes the social aspect (Greif, 1983). Hackman and Oldham (1980) particularly stress the content of work; representative of the sociotechnical system approach (Emery, 1972; Ulich, 1991), the integration of social and technical aspects plays an essential role.

The notion that only the financial aspect is important to workers is widespread. Asking workers themselves, a more differentiated pattern results (Ruiz Quintanilla, 1984; MOW, 1987). When asked about the meaning of various aspects of work in general (keeps me busy, facilitates contacts, is interesting, gives me an income, gives me prestige and status, allows me to serve society), income ranks first, followed by possibilities for contact. Few think that the work itself is interesting and satisfactory. An evaluation of the roles that the tasks, the company, the product, the people, the career, and the money play in one's working life shows that money ranks first again, this time coequally followed by tasks and social contacts. Finally, when asked which of 11 aspects (possibilities to learn, working time, variety, interesting task, job security, remuneration, physical circumstances, and others) is most important to employees, the interesting task has top priority. How should these—at first sight, contrary results—be interpreted?

1.  The great importance that is attached to payment in the first two questions shows that ensuring one's living is seen as a fundamental function of work. It is not surprising that answering the first question, very few people judge work itself as being interesting if one considers that it is about work in general. Work has to fulfill certain conditions to be interesting; it does not obtain this quality automatically.

2.  The second question refers directly to the meaning that the various aspects have in one's own working life. Here, the tasks that one fulfills (i.e., the aspect of content) gain considerable significance.

3.  The third question is directed toward expectations. Here, payment plays an important role, too, but it can now be found on the same level

with other aspects; all are exceeded by one attribute: the desire for an interesting task.

Therefore, remuneration as a fundamental function in terms of income maintenance is of overriding importance for waged work. When talking about one's own working life, it remains the most important aspect, followed by the content of work and the social conditions. Beyond the fundamental function of income maintenance, an exceptionally high remuneration does not have priority; in this context, the aspect of an interesting task ranks first.

## 2 MOTIVATION TO WORK

Science and practice are equally interested in finding out which forces are motivating people to invest energy in a task or a job, in taking up a job at all, in being at the workplace every day, or in working with initiative and interest on the completion of a task. The understanding of work motivation makes it possible to explain why people direct their forces and energy in a certain direction, pursue a set goal, and show certain patterns of behavior and reactions in the job environment of an organization (Heckhausen, 1980; Phillips and Lord, 1980; Wiswede, 1980; McClelland, 1985; Weiner, 1985, 1992; Staw et al., 1986; Katzell and Thompson, 1990; Nicholson et al., 2004).

These considerations about motivation processes in the job environment are predominated by the assumption that behavior and work performance within an organization are influenced and determined by these motivational processes. Although one cannot doubt this observation, it must be noted that motivation cannot be the only determinant of working performance and behavior. Other variables affect the working process of the individual organizational member, too, and a motivation theory also has to take into account such variables as efforts, abilities, expectations, values, and former experiences, to name only a few, if it wants to explain working behavior.

While considering how working behavior is initiated, sustained, stopped, and directed, on which energies it is based and which subjective reactions it can trigger in the organism, most motivation researchers fall back on the two psychological concepts of needs and goals. In doing so, needs are seen as suppliers of energy and trigger the mechanism of the behavioral pattern of a working person. Therefore, a lack of necessities felt by a person at a particular time activates a search process with the intention of eliminating this deficit. Moreover, many theorists assume that the motivation process is goal oriented. Thus, the goal or final result that an employee is striving for in the working process possesses a certain attraction for the person. As soon as the goal is achieved, the lack of necessities is reduced. Thereby, the size of the deficiency is influenced by the individual characteristics of the organizational member (perceptions, personality, attitudes, experiences, values) as well as by a variety of organizational variables (structure, level, span of control, workplace, technology,

leadership, team). The individual characteristics and organizational variables influence the searching behavior shown by an employee trying to attain a goal and determine the amount of energy invested by a person to achieve a goal. The employee will deliver a certain performance that in turn will lead to the expected financial and nonfinancial rewards, and finally, to job satisfaction. It is true that motivation and satisfaction are closely linked, but they are not synonymous. Whereas motivation is to be understood as a predisposition to a specific, goal-oriented way of acting in the working process, job satisfaction is to be seen as a consequence of performance-based rewards. Therefore, the employee can be unsatisfied with the present relation between working behavior, performance, and rewards but might still be highly motivated to fulfill a task, showing initiative, good performance, and working extra hours. In other words, a motivated employee does not have to be satisfied with the various aspects of his or her work.

To a large extent, productivity of organizations depends on the willingness of its employees to use their qualifications in a goal- and task-oriented way. This motivation characterizes an important factor of human productivity in organizations and becomes apparent as quantitative or qualitative work performance as well as in low rates of absenteeism and personnel turnover. As soon as the goals of the organization correspond to those of the employees, the individual motivational states fit into the organizational frame and thus facilitate employee satisfaction. Job and organizational design strive for the creation of conditions under which people can work productively and be satisfied at the same time.

## 3 THEORIES OF WORK MOTIVATION

To explain motivated behavior in the work situation as well as the relationship between behavior and outcome or performance, a series of alternative motivation theories have been developed; some of them are described below. These theories are subdivided into two groups: content theories and process models (Campbell and Pritchard, 1976). The motivation theories of the first category concentrate on the description of the factors motivating people to work. They analyze, among other things, the needs and rewards that drive behavior. In contrast, the process models of work motivation deal primarily with the processes determining execution or omission as well as with the type of execution of an action.

### 3.1 Content Theories

#### 3.1.1 Maslow's Hierarchy of Needs

As a result of psychological experiments and of his own observations, Maslow (1954) formulated a theory that was meant to explain the structure and dynamics of motivation of healthy human beings. In doing so, he distinguished five different levels of needs (Figure 1):

1. *Physiological Needs*. These serve to maintain bodily functions (e.g., thirst, hunger, sexuality,
**Figure 1**  Maslow's levels of needs.

tranquility); they manifest themselves as physical deficiencies and are therefore easy to detect.

2. *Safety Needs*. These appear as the desire for safety and constancy, stability, shelter, law, and order; in industrial nations they emerge in their original form only in disaster situations; however, in a culture-specific form they are omnipresent here as well: as a need for a secure job, a savings account, or several kinds of insurances; as resistance to change; and as a tendency to take on a philosophy of life that allows orientation.

3. *Social Needs*. These needs, such as the desire for affection and belonging, aim at the give and take of sympathy and admission to society.

4. *Esteem Needs*. The satisfaction of these needs results in self-confidence and recognition; their frustration leads to feelings of inferiority and helplessness.

5. *Need for Self-Actualization*. This is the desire of human beings to realize their potential abilities and skills.

According to Maslow, these needs are integrated into a hierarchical structure, with physiological needs as the lowest level and the need for self-actualization as the highest. Maslow combines this hierarchy with the thesis that the elementary needs will take effect first; the contents of the higher levels will become important only when the needs of lower levels are satisfied to a certain extent. Only when need levels 1–4 are satisfied does the need for self-actualization get into focus. The single stages show repletion points (i.e., with adequate satisfaction of needs, motivation by means of this need is no longer possible). Striving for self-actualization is the only motive without satisfaction limits and thus remains effective indefinitely; in contrast to deficiency needs 1–4, it is a need for growth serving the perfection of human personality.

The importance of Maslow's concept has to be seen primarily in his verbalization of self-actualization as a human objective; he thus provoked an ongoing discussion (also in industrial companies). The weak spots of this theory lie especially in the difficulties of operationalization and verification and in the fact that the central concept of self-actualization is kept surprisingly vague. Nevertheless, this model is still very popular among practitioners; in the field of research, a critical reception dominates. The practical effectiveness of Maslow's approach is linked more to its plausibility than to its stringency. Still, it has initiated a number of other concepts or has at least influenced them (e.g., Barnes, 1960; McGregor, 1960; Alderfer, 1969).

The extensive criticism of this model (Neuberger, 1974) shows that especially the fascinating claim for universality cannot be confirmed. Apart from the fact that the categories of needs often cannot be distinguished sufficiently, the criticism alludes primarily to the hierarchical order of the needs and the dynamics of their satisfaction. Summarizing some research projects evaluating the validity of Maslow's model (e.g., Salancik and Pfeffer, 1977; Staw et al., 1986), there is little support for the existence of a need hierarchy:

- Most people differ very clearly regarding the degree to which they want a lower need to be satisfied before they concentrate on the satisfaction of a higher need.
- Several categories of needs overlap, and thus an individual need can fall into various categories at the same time.
- Within certain limits, working people are able to find substitutes for the satisfaction of some needs.
- The opportunities and chances given to an employee in the world of work are of great importance for the striving and intention to satisfy certain needs.

Finally, a number of researchers substantiated the fact that the types of needs that working persons are trying to satisfy within their organizations depend on the occupational group they belong to and their values, goals, and standards as well as on the options for need satisfaction offered within their occupational group. These studies have shown that unskilled workers who are offered few possibilities for autonomous work and promotion within an organization stress job security and physical working conditions a lot more than do members of other professional categories. In comparison, skilled workers emphasize the type of work that satisfies or dissatisfies them. Employees in service companies usually focus on the satisfaction of social needs and, as a consequence, on the job satisfaction derived from their social interactions with colleagues and customers.

Engineers concentrate more on the performance needs at the workplace, whereas accountants in the same companies were more concerned about their promotion, even if the promotion did not result in a financial or other material benefit (e.g., Herzberg et al., 1959). Differences of this type in the pursuit of need satisfaction can be explained partially by the fact that the possibilities for the accountant to be creative at work and to develop self-initiative are a lot more restricted than those of an engineer. A study by Porter (1964) shows that the degree of job satisfaction among executives compared to other professions in the same organization was above average, but executives of lower ranks within the organizational hierarchy were a lot less satisfied with their opportunities to work independently, autonomously, and creatively than were employees of higher ranks in the same organizational hierarchy.

### 3.1.2 Alderfer's ERG Theory

Since numerous analyses demonstrate that an excessive differentiation of needs is difficult to operationalize and that their hierarchical structure can be falsified easily, Alderfer (1972) is of the opinion that Maslow's theory is not fully applicable to employees in organizations. In his ERG theory, he reduced the number of need categories—according to Alderfer, Maslow's model shows overlaps among the safety, social, and appreciation needs—and developed a well-elaborated system of relations between these needs. This contains only three levels of basic needs (Figure 2):

1. *Existence Needs* (*E Needs*). These needs comprise the desire for physiological and material well-being and include Maslow's physiological needs, financial and nonfinancial rewards and remuneration, and working conditions.
2. *Relatedness Needs* (*R Needs*). These needs can be subsumed as desire for satisfying interpersonal relationships and contain Maslow's social needs as well as the esteem needs.
3. *Growth Needs* (*G Needs*). These needs can be described as a desire for continued personal growth and development and as the pursuit of self-realization and productivity; therefore, this category forms an overlap of Maslow's esteem needs and self-actualization.

Maslow defines the motivation process of humans, who are always aspiring for the next-higher need level, as a type of progression by satisfaction and fulfillment of the particular needs: The person has to satisfy a specific need first, before the next higher one is activated. Alderfer includes a component of frustration and regression in his model. Thereby, Alderfer's theoretical assumptions are opposed to Maslow's model in several fundamental aspects: ERG theory does not claim that lower level needs have to be satisfied as a precondition for the effectiveness of higher level needs. Moreover, the need hierarchy now works in the opposite direction as well (i.e., if the satisfaction of higher level needs is blocked, the underlying need is reactivated). ERG theory acknowledges that if a higher level need remains unfulfilled, the person might regress to lower level needs that appear easier to satisfy. According to Alderfer's hypothesis of frustration, the power of a need is increased by its frustration, but there is no mandatory association between the needs of the various categories. Therefore, needs already satisfied also serve as motivators as long as they are a substitute for still unsatisfied needs. Another difference is that, unlike Maslow's theory, ERG theory contends that more than one need may be activated at the same time. Finally, ERG theory allows the order of the needs to be different for different people.

The two concepts of fulfillment progression and frustration regression are both constituents of the dynamics

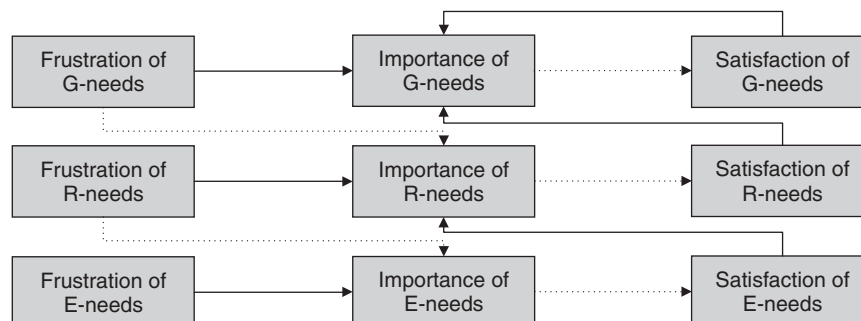

**Figure 2** Alderfer's ERG theory.

of ERG theory. As a consequence of the diverging assumptions of Maslow and Alderfer, different explanations and prognoses about the behavior of employees at their workplace are possible (e.g., Schneider and Alderfer, 1973; Guest, 1984). So far, a completely satisfying proof, especially of the psychological progression and regression processes, has not been successful. On the other hand, the relatively primitive classification of the three needs shows it to be surprisingly acceptable and able to discriminate in several international studies (Elizur et al., 1991; Borg et al., 1993). According to the authors' results, international comparison demonstrates that in case of a lack of financial means and poverty of employees in a certain region the phenomena that are attributed to the complex "existence" come to the fore, whereas in saturated societies especially, growth needs are dominant.

### 3.1.3  McGregor's X and Y Theory

McGregor (1960) supported a direct transfer of Maslow's theory to job motivation. He objected to a theory X that was derived from managerial practice. It starts from the following assumptions: The tasks of management concerning personnel consist in the steering of its performance and motivation as well as in the control and enforcement of company goals. Since without these activities employees face a company's goals in a passive way or resist them, it is necessary to reward, punish, and control. Therefore, a principally negative view of employees prevails among managers. In detail, this view is determined by the wrong ideas that the average person is lazy and inactive, lacks ambition, dislikes responsibility, is egocentric by nature and indifferent to the organization, is greedy and money

oriented, objects to changes from the outset, and is credulous and not very clever.

According to McGregor, this concept of management is destructive for employees' motivation. Hence, McGregor drafts an antithesis building on Maslow's need hierarchy, naming it theory Y. Essentially, it contains the following assumptions: (1) observable idleness, unreliability, dislike of responsibility, and material orientation are consequences of the traditional treatment of the working person by management and (2) motivation in terms of potential for development, the willingness to adapt to organizational goals, and the option to assume responsibility exists in every person, and it is the fundamental task of management to create organizational conditions and to point out ways that allow employees to reach their own goals best when bringing them into agreement with the company's goals.

McGregor proposes the following measures that can ease the restrictions of the possibilities of satisfaction for the employees and facilitate responsible employment for the purpose of Maslow's ideal conception: (1) decentralization of responsibility at the workplace, (2) participation and a consulting management, and (3) involvement of employees in control and evaluation of their own work.

### 3.1.4  Herzberg's Two-Factor Theory

The motivation theory developed by Herzberg et al. (1959) is probably the most popular theory of work motivation (Figure 3). Its central topic is job satisfaction. Results of empirical studies led Herzberg and his colleagues to the opinion that satisfaction and dissatisfaction at the workplace are influenced by various groups of factors. Dissatisfaction does not occur simply

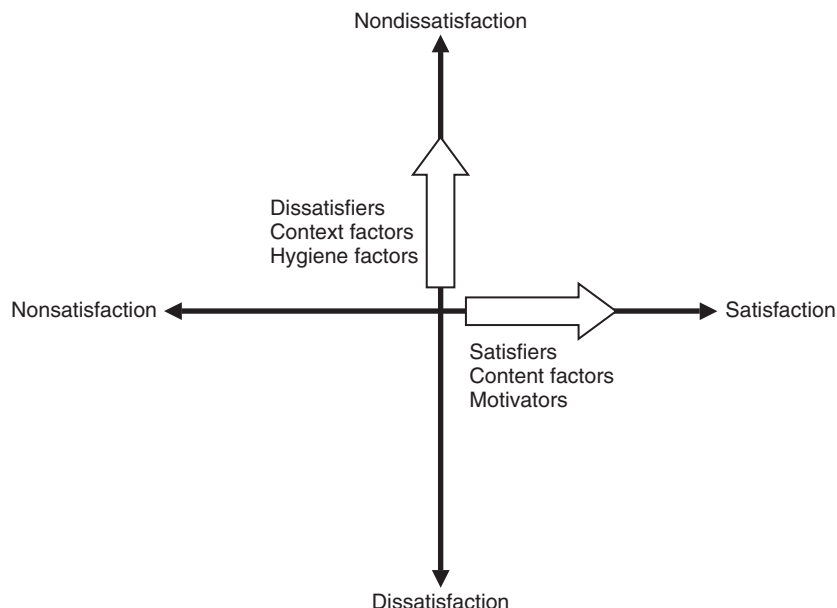

**Figure 3**  Herzberg's two-factor theory.

because of the lack or insufficient value of parameters that otherwise cause satisfaction. Herzberg called the factors that lead to satisfaction *satisfiers*. These are primarily (1) the task itself, (2) the possibility to achieve something, (3) the opportunity to develop oneself, (4) responsibility at work, (5) promotion possibilities, and (6) recognition.

Since these factors are linked directly to the content of work, Herzberg also referred to them as *content factors*. Due to the fact that their positive value leads to satisfaction and consequently motivates for performance, they were seen as the actual motivators. According to Herzberg, for the majority of employees, motivators serve the purpose of developing their professional occupation as a source of personal growth.

In contrast, *dissatisfiers* have to be assigned to the working environment and are therefore also called *context factors*. According to Herzberg, they include especially (1) the design of the surrounding working conditions, (2) the relationship with colleagues, (3) the relationship with superiors, (4) company policy and administration, (5) remuneration (including social benefits), and (6) job security. Since the positive values of these parameters accommodate the employees' need to avoid unpleasant situations in a preventive way, they were also referred to as *hygiene factors*. In many cases content factors allude to intrinsic motivation and context factors to extrinsic motivation.

Since Herzberg's theory also suggests a number of practical solutions to organizational problems and allows predictions about behavior at the workplace to a certain extent and because of the impressive simplicity of the model and its orientation toward the terminology of organizational processes, a large variety of empirical studies have been undertaken to examine the underlying postulates and assumptions (e.g., Lawler, 1973; Kerr et al., 1974; Caston and Braito, 1985). However, many of these studies raised additional questions. The essential objections that can be put forward against Herzberg's model are:

- The restricted validity of data, being based on a small number of occupational groups (only engineers and accountants)
- The oversimplification of Herzberg's construct of motivation or job satisfaction (e.g., satisfaction and dissatisfaction could be based on the working context as well as on the task itself or on both equally)
- The division of satisfaction and dissatisfaction into two separate dimensions
- Lack of consideration of unconscious factors that can have an effect on motivation and dissatisfaction
- Lack of an explanation of why different extrinsic and intrinsic work factors are to influence the performance in a negative or positive way and why various work factors are important
- Lack of consideration of situational variables
- No measurement of job satisfaction as a whole (it is very possible that somebody dislikes parts of his or her job but still thinks that the work is acceptable as a whole)

Existing studies about Herzberg's theory have left many problems unsolved, and it is doubtful whether a relatively simple theory such as Herzberg's can ever shed light on all the questions that are raised here. Despite this criticism, the theory, although being an explanation for job satisfaction rather than a motivation theory, is still very popular. Despite restrictions regarding the methodology and content of this theory, it can be stated that motivators offer a greater motivational potential to intrinsically motivated employees than extrinsic incentives do (e.g., Zink, 1979). Especially when described in a shortened way, Herzberg's concept obviously has such a high plausibility that in industry it still has an astonishing repercussion. The importance of Herzberg's approach is to be seen primarily in the fact that he set the content of work as the focus of attention. This gave numerous companies food for thought and induced manifold change processes. Last but not least, the emphasis on work content had an effect on the dissemination of the so-called *new forms of work design* (Miner, 1980; Ulich, 1991).

### 3.1.5 Hackman and Oldham's Job Characteristics Model

Behavior and attitudes of employees and managers can be influenced to a great extent by a multitude of context variables. Moreover, during recent years the connection and adequate fit of task characteristics or work environment, on the one hand, and the psychological characteristics of the person, on the other (person–job fit), have been studied very intensively and from many different perspectives. Task and work design, especially, formed the focus of interest. These studies were initiated particularly by a motivation model of job and task characteristics (the job characteristics model of work motivation) (Figure 4) developed by Hackman and Oldham (1976, 1980). The model postulates that certain core dimensions of work lead to certain psychological states of the working person which result in specific organizational or personal outcomes. Hackman and Oldham list five job characteristics that cause enhancement of motivation and a higher degree of performance and job satisfaction. Furthermore, they propose that persons with a strong psychological growth need react in a more positive way to tasks containing many core dimensions than do people with a weak growth need. Here, direct reference to Maslow's need hierarchy becomes obvious. A person who currently prioritizes the need for self-actualization is categorized as strong with regard to his or her growth need, whereas somebody operating on the level of safety needs would be seen as somebody with a weak growth need.

The core dimensions of work are the following:

- *Skill variety*: degree to which tasks require different skills or abilities
- *Task identity*: degree to which a person completes a connected piece of work or a task instead of parts or facets of it

*Core job dimensions*          *Critical psychological states*          *Outcomes*

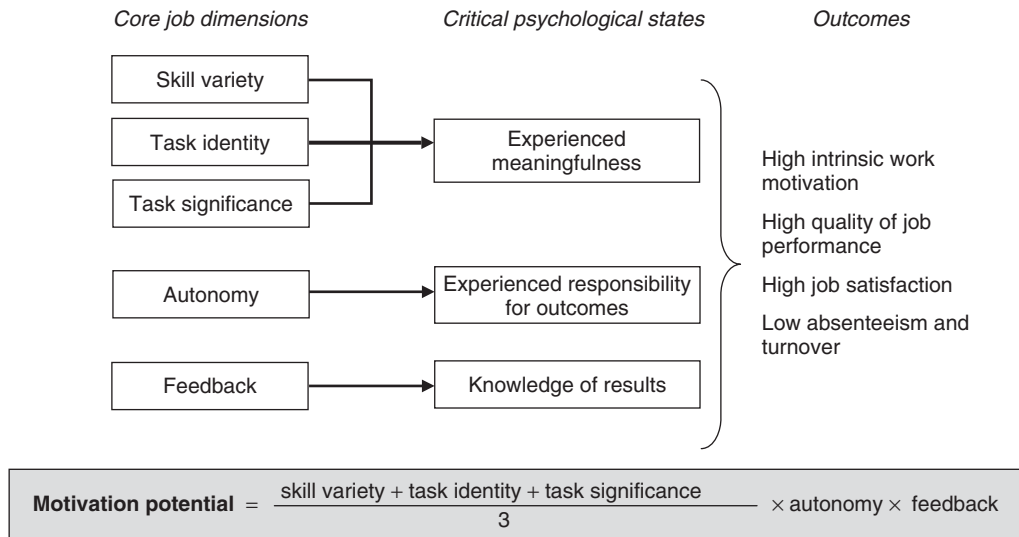
$$\text{Motivation potential} \; = \; \frac{\text{skill variety} + \text{task identity} + \text{task significance}}{3} \; \times \text{autonomy} \times \text{feedback}$$


**Figure 4**  Job characteristics model.

- *Task significance*: degree to which work has an effect on the lives and jobs of others
- *Autonomy*: freedom and independence in the accomplishment of work
- *Feedback*: degree to which work provides clear and direct information about success and effectiveness of the performing person

Summarizing these core dimensions, they result in an index of motivational potential of a job by which jobs can be assessed regarding their possibilities to motivate. But this also makes it possible to compare and classify entire work processes depending on whether they are able to help a person to achieve professional and intellectual growth as well as further development. The score can be seen as a measure of adequacy, quality, and success of the present work design. The formula postulates an additive relation for skill variety, task identity, and task significance whereby the single dimensions can compensate for each other. The multiplicative connection between autonomy and feedback does not allow this and can in an extreme case reduce the motivational potential score to zero. Although other authors affirm the strong emphasis on feedback only with reservations, the formula sharply covers important effects on motivation. In many cases an additive combination of the variables shows it to be on a par with the postulated multiplicative formula.

In the center of the model are the *critical psychological states*. These are defined as follows:

- *Meaningfulness of work*: degree to which a person experiences work in general as meaningful, valuable, and worthwhile
- *Responsibility for outcomes*: degree to which a person feels personally responsible for the work that he or she is doing

- *Knowledge of results*: degree to which a person is continually informed about how successful and effective the job done is

When these states are on an acceptable level, it can be presumed that the person feels good and reacts in a positive way toward the job. It is expected that the dimensions skill variety, task identity, and task significance influence the meaningfulness of work experienced by a person. The dimension autonomy presumably affects the experienced responsibility for outcomes. Feedback contributes to knowledge of the actual results. The critical psychological states for their part determine a variety of personal and work outcomes. Several studies show correlations with intrinsic motivation, job satisfaction, absenteeism, and turnover but only low correlations with quality of job performance. Finally, it is assumed that the growth need strength of an employee mediates relations among the other elements of the theory.

To test the theory empirically, Hackman and Oldham (1975) developed the Job Diagnostic Survey (JDS). This instrument allows objective measurement of job dimensions and measures the various psychological states caused by these characteristics, the affective responses to these job characteristics, and the strength of the personal need to grow and to develop oneself. The JDS can be used to identify workplaces or work structures with a high or low motivational potential. Since the motivational potential score provides a comprising index for the overall motivational potential of a job, a low score points to jobs that deserve redesign. For implementation of the theory in practice, a set of action principles has been developed that give instructions about how the core dimensions of work can be improved (Hackman and Suttle, 1977). In practice, the model has reached a comparably high degree of popularity and is used for the improvement of tasks and job design as often as

Herzberg's model. Therefore, scientific literature concerning this model is very extensive (e.g., Fried and Ferris, 1987; Fried, 1991).

Although research has so far supported the model on the whole, the model contains a number of unsolved problems and methodological weaknesses on which further research will have to focus (Roberts and Glick, 1981). There are questions about the tools that measure the various components of the model, about the significance and modality of computation of the motivational potential score, and about the theoretical foundation on which the model is based. It has to be asked whether the five core dimensions measured with the JDS are really independent (Idaszak and Drasgow, 1987; Williams and Bunker, 1993). In addition, the assumed impact of employees' growth need strength has to be examined, especially its significance and direction. Empirical evidence has to be provided as to which way the critical psychological states are caused or influenced by the five core dimensions of work. Although the formula for the computation of motivational potential suggests considerable interactions among the different job characteristics, it is just as possible that employees tend to ascribe more weight to job characteristics that are most beneficial to them (e.g., autonomy, variety). Furthermore, the mediating function of the psychological states is still quite indistinct (Hackman and Oldham, 1980; Miner, 1980; Udris, 1981).

### 3.1.6 McClelland's Theory of Acquired Needs

McClelland's theory of acquired needs (McClelland, 1984, 1985; McClelland et al., 1989) is closely linked to the psychological concepts of learning and is based to a great extent on the works of Murray (1938). McClelland holds the view that many needs are learned by dealing with and mastering the cultural environment in which a person is living (McClelland, 1961). Since these needs are learned from early childhood on, working behavior that is rewarded will occur more often. Applied to an organization, this means that employees can be motivated, by financial and nonfinancial rewards, to be at their workplace on time and regularly as long as these rewards are linked directly to the favored working behavior. As a result of this learning process, people develop certain need configurations that influence their working behavior as well as their job performance.

Together with other researchers (e.g., Atkinson and Feather, 1966), McClelland filtered those needs out of Murray's list of human needs that in his opinion represent the three key needs in human life: (1) the need for achievement (n-ach), (2) the need for affiliation (n-affil), and (3) the need for power (n-pow). These three unconscious motives have a considerable effect on both the short- and long-term behavior of a person (McClelland et al., 1989). The need for achievement is relevant for change behavior and contains continuous improvement of performance. The need for affiliation is important for group cohesion, cooperation, support, and attractiveness in groups. The need for power is of importance for persuasiveness, orientation toward contest and competition, and readiness to combat. There is an important link to the role of a manager that

consists essentially of activating these motivations and thus energize and guide the behavior of subordinates.

The main interest focuses on the need for achievement, and as a consequence, a theory of achievement motivation was formulated (Atkinson and Feather, 1966) that was applied widely in organizational psychology (Stahl, 1986). Achievement motivation corresponds to a relatively stable disposition of behavior or a potential tendency of behavior of an employee in an organization to strive for achievement and success. However, this motivation becomes effective only when being stimulated by certain situational constellations or incentives that lead a person to assume that a certain working behavior will produce the feeling of achievement. The final result is an inner feeling of satisfaction and pride of achievement. The model developed for this purpose is in effect an expectancy–valence model of motivation processes. Working behavior is understood as the resultant of (1) motivation strength, (2) the valence or attractiveness of the incentive that activates motivation, and (3) a person's expectancy that a certain behavior will lead to gaining the incentive. Hence, the corresponding motivation model can be designed as follows:

$$T_S = M_s \times P_s \times I_s$$

A person's tendency ($T_S$) to approach a task is a multiplicative function of the person's strength of the achievement motivation ($M_s$), the subjective probability of success ($P_s$), and the valence or degree of attractiveness of this success or reward ($I_s$). From this assumption, a set of conclusions can be deduced for the processes of job design not only for the selection and promotion of organizational members but also for the preference of certain leadership styles and for the motivation of risk behavior among managers in decision situations (McClelland et al., 1989).

Empirical research on McClelland's model is extensive and shows a set of consistent results. Here are some examples: People who are highly achievement motivated (have high scores on n-ach) prefer job situations in which they bear responsibility, get feedback on a regular basis, and that ask for a moderate attitude toward risks. Such a constellation has a very motivating effect on high achievers. These kinds of people are active mainly in self-dependent fields of activities. Restrictively, it has to be added, though, that high achievers often show less interest in influencing the achievement of others than in personally seeking high achievements. This is why they often are not good as managers. Reciprocally, managers of big companies rarely are n-ach people. The constellation looks a lot different when considering the need for affiliation or for power. Research shows that successful managers frequently have a high need for power and a rather low need for affiliation, a constellation that probably is necessary for efficiency of leadership and that can possibly be deduced from the function or role within the organizational context (Parker and Chusmir, 1992). Finally, Miron and McClelland (1979) point out that for the filling of positions that require a high need for achievement, a combination of selection and training is advised. People with high n-ach scores are selected and

developed by means of achievement trainings with the goal of imparting to these persons a pattern of thought in terms of achievement, success, and profit and to act upon this pattern. The three secondary or learned motivations investigated proved to be very informative and stable with regard to the explanation of working behavior and leadership. However, it is possible that the explication of organizational behavior can be improved by other secondary motives. This applies especially in the area of managerial functions. Therefore, Yukl (1990) adds two more secondary motives to his description of skills, characteristics, and goals of successful managers: the need for security and the need for status. For a better illustration, the five key motivations and their descriptors are listed below:

1. Need for achievement
   - To excel others
   - To attain challenging goals
   - To solve complex problems
   - To develop a better method to do a job
2. Need for power
   - To influence others to change their attitudes and behavior
   - To control people and things
   - To have a position of authority
   - To control information and resources
3. Need for affiliation
   - To need to be liked by others
   - To be accepted as part of a group
   - To relate to others in a harmonious way and to avoid conflicts
   - To take part in enjoyable social activities
4. Need for security
   - To have a secure job
   - To be protected against loss of income
   - To avoid tasks and decisions that include risks or failures
   - To be protected against illness and incapacity for work
5. Need for status
   - To have the right car and to wear the right clothes
   - To work for the right company in the right position
   - To have the privileges of leaders
   - To live in the right neighborhood and to belong to the right club

### 3.1.7   Argyris's Concept

An approach that joins different concepts together is that of Argyris (1964). According to Argyris, work motivation, the competency to solve problems, and emotional well-being are facilitated primarily by a feeling of self-esteem based on *psychological success*. The possibility of defining one's own goals according to one's own needs and values and to control goals in a self-dependent way operates as an important precondition for psychological success. From this emanates a contradiction to the structures of the formal organization that work such that a single employee can control his or her own working conditions to a minimal extent only, that he or she can bring in only a few or very limited skills in his or her work, and that he or she can behave only in a very dependent way.

Only if organizations believe that employees want to apply their skills in the framework of the company's goals and that they want to get involved in relevant decisions will employees be able to behave like grown-ups. On the other hand, if companies are structured differently, employees will behave accordingly: dependent, with little interest, with a short-term perspective; independence of thinking and acting might find their expression only in the development of defense.

Argyris's contribution contains a variety of unclarified points (Greif, 1983). As for Maslow and Herzberg, it is also true for Argyris that interindividual differences are largely disregarded in their concrete meaning for the development of job and organizational structures.

### 3.1.8   Deci and Ryan's Self-Determination Theory

Another metatheory of motivation and personality, the self-determination theory (SDT) of Deci and Ryan (1985), is based on the assumption that humans naturally strive for psychological growth and development. While mastering continuous challenges, the social context plays a vital role; its interaction with the active organism allows predictions about behavior, experience, and development. Deci and Ryan postulate three motivating factors that influence human development: (1) the need for autonomy, (2) the need for competence, and (3) the need for relatedness. They are referred to as basic psychological needs that are innate and universal (i.e., they apply to all people, regardless of gender, group, or culture).

The need for autonomy refers to people's striving for self-determination of goals and actions. Only when perceiving oneself as the origin of one's own actions and not being at the mercy of one's environment can one feel motivated. The successful handling of a task will be perceived as the confirmation of one's own competence only if it was solved mainly autonomously. The need for competence expresses the ambition to perceive oneself as capable of acting effectively in interaction with the environment. The need for relatedness has a direct evolutionary basis and comprises the close emotional bond with another person.

When these three needs are supported by social contexts and are able to be fulfilled by individuals, well-being is reinforced. Conversely, when cultural, contextual, or intrapsychic forces inhibit the fulfillment of the three basic needs, well-being is reduced. In this theory, motivation is seen as a continuum from amotivation to extrinsic motivation to intrinsic motivation. According to SDT, autonomy, competence, and relatedness are

three psychological nutriments that facilitate the progression from amotivation to intrinsic motivation (Ryan and Deci, 2000; Deci, 2002).

SDT contains four subtheories that have been developed to explain a set of motivational phenomena that has emerged from laboratory and field research:

- *Cognitive evaluation theory*: deals with the effects of social contexts on intrinsic motivation
- *Organismic integration theory*: helps to specify the various forms of extrinsic motivation and the contextual factors that either promote or prevent internalization
- *Causality orientations theory*: pictures individual varieties in people's tendencies toward self-determined behavior and toward directing to the environment in a mode that supports their self-determination
- *Basic needs theory*: develops the idea of basic needs and their connection to psychological health and well-being

Cognitive evaluation theory (CET), for example, aims at specifying factors that explain variability in intrinsic motivation and focuses on the need for competence and autonomy. *Intrinsic motivation* means to do an activity for the inherent satisfaction of the activity itself and thus differs from *extrinsic motivation*, referring to the performance of an activity to attain some separable outcome (Ryan and Deci, 2000). According to CET, social-contextual events (e.g., feedback, communication, rewards) conducive to feelings of competence and autonomy during action can enhance intrinsic motivation. Studies showed that intrinsic motivation is facilitated by optimal challenges, effectance-promoting feedback, and freedom from demeaning evaluations (e.g., Deci, 1975; Vallerand and Reid, 1984). However, the principles of CET do not apply to those activities that do not hold intrinsic interest and that do not have the appeal of novelty, challenge, or aesthetic value (Ryan and Deci, 2000).

Contrary to some studies, Deci does not assume an additive connection between intrinsic and extrinsic motivation. Rather, he postulates an interaction between both types of motivation, which means that extrinsic incentives can replace intrinsic motivation (Vansteenkiste and Deci, 2003). In his studies he tested the following hypotheses:

1. If intrinsic motivation makes a person perform an action and this action is recompensed with an extrinsic reward (e.g., money), his or her intrinsic motivation for the particular action decreases.

2. If intrinsic motivation makes a person perform an action and this action is recompensed with verbal encouragement and positive feedback, his or her intrinsic motivation for this particular action increases.

The design of Deci's studies has always been the same: An extrinsic incentive is added to an interesting activity. Then the variance of the intrinsic motivation has been measured on the basis of the dependent variable. He concludes that his experimental results support the hypotheses mentioned above. Money seems to have a negative impact on intrinsic motivation. Verbal encouragement and positive feedback, on the other hand, have a positive impact.

Self-determination theory has been applied within very diverse domains, such as health care, education, sports, religion, and psychotherapy, as well as in industrial work situations. For example, Deci et al. (1989) found that managers' interpersonal orientations toward supporting subordinates' self-determination versus controlling their behavior, correlated with their subordinates' perceptions, affects, and satisfactions. Moreover, the evaluation of an organizational development program focusing on the concept of supporting subordinates' self-determination showed a clearly positive impact on managers' orientations but a less conclusive impact on subordinates. Later studies on the topic of supervisory style support these findings: Participants experienced higher levels of intrinsic motivation under conditions of an autonomy-supportive style than of non-punitive controlling and punitive controlling supervisory styles (Richer and Vallerand, 1995). Researchers were also able to show that the constructs of SDT were equivalent across countries as well. Deci et al. (2001) found that a model derived from SDT in which autonomy-supportive work climates predict satisfaction of the intrinsic needs for competence, autonomy, and relatedness, which in turn predict task motivation and psychological adjustment on the job, was valid in work organizations in the United States as well as in state-owned companies in Bulgaria.

Among the three needs, autonomy is the most controversial. Iyengar and Lepper (1999) presume that cultural values for autonomy are opposed to those of relatedness and group cohesion. They provided experimental evidence showing that the imposition of choices by an experimenter relative to personal choice undermined intrinsic motivation in both Asian Americans and Anglo Americans. However, they also showed that adopting choices made by trusted others uniquely enhanced intrinsic motivation for the Asian group. Their interpretation focused on the latter findings, which they portrayed as challenging the notion that autonomy is important across cultures. Oishi (2000) measured autonomy by assessing people's individualistic values, apparently assuming them to represent autonomy as defined within SDT. On the basis of this measure, Oishi reported that outside of a very few highly individualistic Western nations, autonomous persons were not more satisfied with their lives. Finally, Miller (1997) suggested that in some cultures adherence to controlling pressures yields more satisfaction than does autonomy. Her characterizations of autonomy, like those of Iyengar and Lepper and Oishi, do not concur with SDT's definition.

### 3.1.9  Summary of Content Theories

So far it has not been possible to provide evidence that certain motives are universal. More promising seems the identification of dominant motives or constellations for

certain groups of persons (Six and Kleinbeck, 1989). French (1958) shows, for example, that praise is more effective when its content addresses the dominant motive: Praise for efficiency leads to a better performance in achievement-motivated people, praise for good cooperation, in affiliation-motivated people. Other studies support the importance of the congruence of the person's motivation structure and the organization's structure of incentives.

It is neither possible nor reasonable to fix the number of motivating factors at work once and for all; the differentiation has to differ depending on the purpose of analysis and design. It is striking, though, that from many analyses two factors of higher order result that correspond to a large extent to Herzberg's factors (content and context) (Campbell and Pritchard, 1976; Ruiz Quintanilla, 1984). All concepts mentioned have pointed out the importance of intrinsic motivation by means of holistic and stimulating work contents (Hacker, 1986; Volpert, 1987; Ulich, 1991). The complexity of the problem makes it impossible to choose a theory that is able to serve as an exclusive basis for a satisfying explanation of working behavior in organizations. All theories have in common that they try to explain the "what" of energized behavior, that they recognize that all people possess either congenital or learned and acquired needs, and finally that they reveal nothing about "how" behavior is energized and directed.

## 3.2   Process Models

These motivation theories try to answer the question of how human behavior is energized, directed, and stopped and why humans choose certain ways of behavior to reach their goals. They differ from the content theories especially by stressing cognitive aspects of human behavior and postulating that people have cognitive expectations concerning the goal or final result that is to be reached. According to these instrumentality theories, humans only decide to act if they can achieve something that is valuable for them, and thus an action becomes instrumental for the achievement of a result to which a certain value is attached.

### 3.2.1   Vroom's VIE Theory

Vroom (1964) refers to his instrumentality theory as VIE theory. The central part of this theory is constituted by the three concepts of valence (V), instrumentality (I), and expectancy (E). *Valence* describes the component comprising the attracting and repellent properties of the psychological object in the working environment—payment has a positive, danger a negative valence. Thus, before a job action is initiated, the person is interested in the value of the final result. This valence reflects the strength of the individual desire or the attractiveness of the goal or final result for the person that can be reached by different means. To be able to explain the processes in this situation of selection of alternative actions, Vroom establishes the idea of a result on a first level and a result on a second level. Thereby, the functions of the two other components, instrumentality and expectancy, are defined. An employee may assume that if he or she does a good job, he or she

will be promoted. The degree to which the employee believes in this is an estimation of subjective probability, referred to as *expectancy*. Finally, the expectancy of a person relates to his or her assumed probability that a certain effort will lead to a certain outcome. Thus, in attaining the goal of the first level, the person sees a way to reach the goal of the second level. According to this, the considerations of Vroom's motivation model can be phrased as follows: The valence of the result of the first level (e.g., effort) is determined by the person's estimation of the probability that this first-level result will lead to a row of second-level results (e.g., pay raise or promotion) and the valences linked to it.

Thus, Vroom's model (Figure 5) states that motivation or effort put in by a person to reach his or her goals are a function of his or her expectancy that as a result of his or her behavior a certain outcome will be achieved and of the valence that the result has. If one of the two factors is zero, there is no motivational force and an action for the achievement of a certain result will not take place. Hence, this motivation model provides very concrete explanations for the working behavior of employees in organizational practice. In this context it is important to emphasize that the direct explanations of the VIE model do not refer to working results or job performance but to motivated behavior—to decision making and effort in particular. As to this, the model can be seen as confirmed to a rather wide extent; expected connections to performance are not that strong because there are several mediators between effort and result that have to be taken into account. To make some good explanations with the help of this model, there has to be an appropriate organizational environment; outcomes of actions and their consequences for the persons concerned have to be transparent and calculable consistently. This is where to find important practical implications of the model for leadership and organizational design.

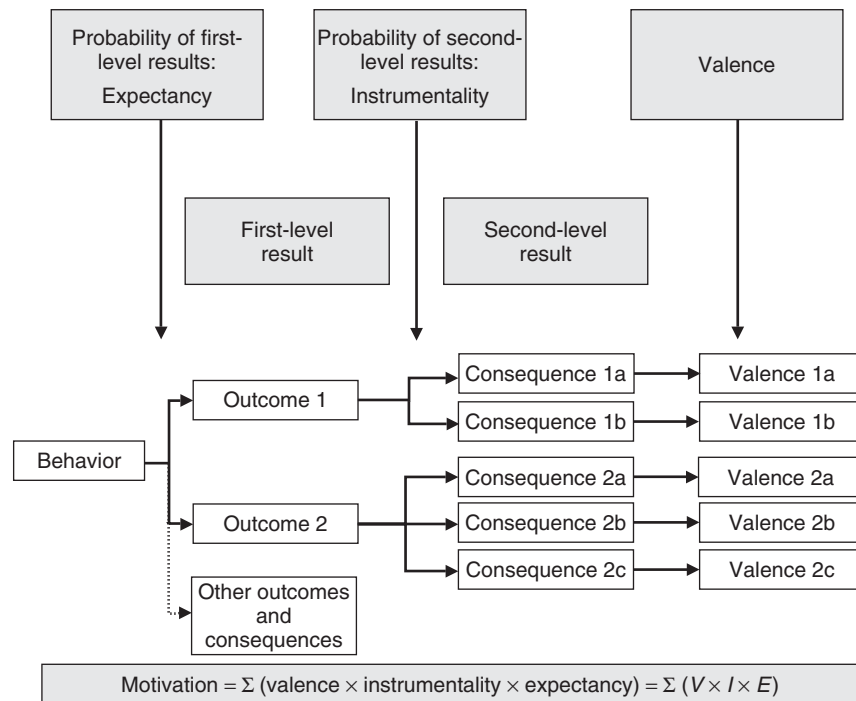
However, despite the advantages offered by Vroom's motivation model, there are some unsolved problems inherent in the model as well that restrict its explanatory power. For example, Vroom provides no information about the effect of those factors that influence the expectancy of an organizational member (e.g., self-esteem, former experiences in similar situations, abilities, leadership). It is also possible that employees misjudge a work situation, possibly because of their needs, emotions, values, or assumptions. This situation may result in employees choosing a nonadequate behavior and in not considering all factors that are relevant. In addition, it could be put forth against Vroom's ideas that to date there has been no research effort to determine how expectations and instrumentalities develop and by which factors they are influenced. Furthermore, the specific operation mode of the model is too complex and too rational to represent human calculations in a realistic way. Besides, an additive model works just as well as a multiplicative one. Altogether, the particular value of the model is that it points out the importance of multiple results or consequences with their probabilities and appraisal being different for each person. In this


**Figure 5**  Vroom's VIE theory.

respect, it turns against perceptions that are too simple and according to which few motives virtually lead directly to actions and suggests a more complex strategy of analysis.

### 3.2.2  Porter and Lawler's Motivation Model

Among the process models, Porter and Lawler's (1968) model and in succession those of Zink (1979) and Wiswede (1980) have to be pointed out. They consider satisfaction, among other things, as a consequence of external rewards or, with intrinsic motivation, of self-reward for results of actions. The value of these models, which try to integrate various social–psychological principles (e.g., social matching processes, aspiration level, self-esteem, attribution, role perceptions, achievement motivation), is to offer a heuristically effective framework in which relevant psychological theories are related in a systematic way to explain performance and satisfaction.

Porter and Lawler's motivation model (Figure 6) is closely related to Vroom's ideas but focuses more on the special circumstances in industrial organizations. It is a *circulation model* of the relationship between job performance and job satisfaction. With this model, Porter and Lawler describe working behavior in organizations by emphasizing the rational and cognitive elements of human behavior that have been ignored, especially by the content theories. This is particularly true with regard to planning and decision making regarding anticipated future events at the workplace. The two crucial points in this model are:

- *The subjective probability* $E \rightarrow P$: the expectation to achieve a goal with greater effort
- *The probability* $P \rightarrow O$: a good performance will lead to the desired output, considering the valences of these goals

Thus, Porter and Lawler postulate that the motivation of an organizational member to do a good job is determined essentially by two probability factors: by the subjective estimated values $E \rightarrow P$ and $P \rightarrow O$. In other words the individual motivation at the workplace is determined by the probabilities that increased effort leads to better performance and that better performance leads to goals and results that have a positive valence for the person. Moreover, Porter and Lawler state that the two probabilities $E \rightarrow P$ and $P \rightarrow O$ are linked to each other in a multiplicative way. But this multiplicative relationship says as well that as soon as one of the two factors is zero the probability relation between effort and final result also decreases to zero. Explications for observable behavior at the workplace that can be derived from this are evident.

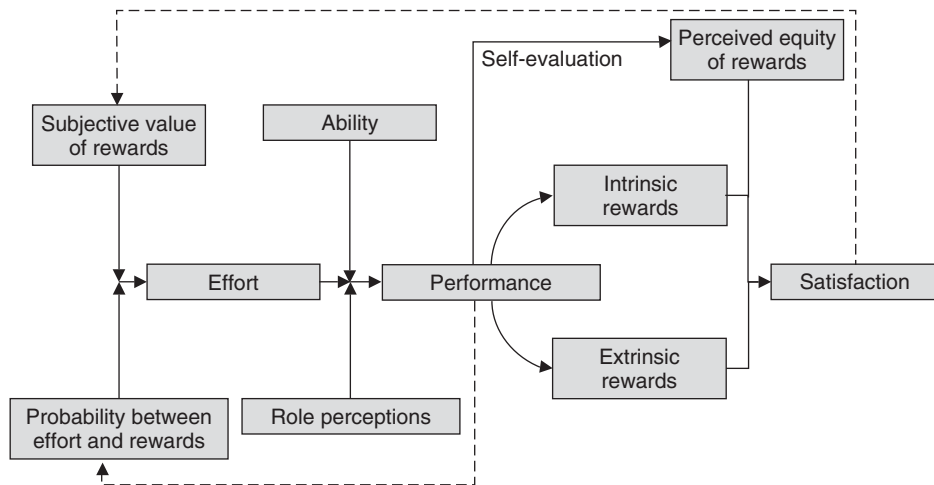
In this model the first component, subjective value of rewards, describes the valence or attractiveness that different outcomes and results of the work done have for the person—different employees have different values for different goals or results. The second component, probability between effort and rewards, refers to the subjective probability with which a person assumes that an increase in effort leads to the receipt of certain results of rewards and remuneration considered as


**Figure 6**  Porter and Lawler's motivation model.

valuable and useful by the person. This estimated probability contains in the broader sense the two subjective probabilities specified above: $E \rightarrow P$ and $P \rightarrow O$. The third component of the model consists of the effort of an organizational member to perform on a certain level. In this point, Porter and Lawler's motivation model differs from former theories because it distinguishes between effort (applied energy) and work actually performed (efficiency of work performance). The fourth component, the area of individual abilities and characteristics (e.g., intelligence or psychomotoric skills), has to be mentioned. It sets limits on an employee's accomplishment on a task. These individual characteristics, which are relatively stable, constitute a separate source of interindividual variation in job performance in this model. Role perceptions are based primarily on how an employee interprets success or successful accomplishment of a task at the workplace. They depend on what and in which direction a person will focus his or her efforts. In other words, role perceptions directly influence the relationship between effort and quality of job performance. This is why inadequate role perceptions lead to a situation where an employee obtains wrong or useless work results while showing great effort. Finally, the accomplishment of a job constitutes a sixth component that refers to the level of work performance an employee achieves. Although task execution and work performance play such an important role in organizations, the components themselves, as well as their interactions, are often misunderstood, oversimplified, and wrongly interpreted. Successful accomplishment of a task is, as Porter and Lawler's model shows, influenced by multiple variables and their interactions. It is the resultant of a variety of components and a combination of various parameters and their effects. The component reward consists of two parts: the intrinsic reward, given by oneself, and the extrinsic reward, essentially (but not exclusively) given by a superior. An intrinsic reward is perceived only if the person believes that he or she has mastered a difficult task. On the other

hand, an extrinsic reward can be perceived only if the successful execution of a task is noticed and valued accordingly by a superior, which is often not the case. The last two components of the model are the reward seen as appropriate by the employee and the "satisfaction" of the employee. This component, perceived equity of rewards, refers to the amount of the reward that the employee, based on performance, expects as appropriate and fair from the organization. The degree of satisfaction can be understood as the result of the employee's comparison of the reward actually obtained to the reward considered as appropriate and fair as compensation for the job done. The greater the difference between these two values, the higher will be the degree of satisfaction or dissatisfaction.

The model developed by Porter and Lawler shows in a striking way that a happy employee is not necessarily a productive one. Numerous empirical studies prove the correctness of the assumptions of the model in its essential points (Podsakoff and Williams, 1986; Locke and Latham, 1990; Thompson et al., 1993; Blau, 1993).

Finally, it has to be stated that in the underlying formula of performance, $P = f(M \times A)$ (i.e., performance is a function of the interaction of motivation and ability), another important parameter has been ignored. If we want to explain and predict work performance, it seems more realistic to consider the possibility of achieving a certain goal and showing a certain performance as well. Even if a person is willing and able to do a good job, there might be obstacles reducing or even thwarting success. This is why the formula has to be broadened to $P = f(M \times A \times O)$. A lack of possibilities or options to achieving maximum performance can be found in any work environment. They range from defective material, tools, devices, and machines to a lack of support by superiors and colleagues and inhibiting rules and processes or incomplete information while making decisions.

The model of Porter and Lawler points out precise fields of application in practice: Each component is practicable and the processes are just as easy to understand and to see through. Organizational management can influence the relationship between effort and reward by linking reward directly to work performance. Moreover, it is possible to influence virtually every component in a systematic way because, according to Porter and Lawler, the effects are predictable within certain limits.

### 3.2.3 Adams's Equity Theory

In contrast to the instrumentality theories, which deal essentially with the expectancies of a person at the workplace and with how these expectations influence behavior, the balance theories of motivation focus on interindividual comparisons and on states of tension and their reduction. These are already the general assumptions of this type of motivation model: Behavior is initiated, directed, and sustained by people's attempts to find a kind of internal balance (i.e., to keep their psychological budget balanced). Festinger's (1957) theory of cognitive dissonance serves as a basis for the various versions of balance theories especially designed for work organizations. Simplified, Festinger postulates that discrepant cognitions cause psychological tensions that are perceived as unpleasant and that humans act to reduce these tensions. Hence, if a person has two inconsistent cognitions, the person falls into an aversive state of motivation called *cognitive dissonance*.

The central idea of Adams's equity theory (Adams, 1963, 1965), which has been applied primarily in work organizations and has often been examined (Mikula, 1980), is that employees of an organization make comparisons, on the one hand, between their contributions and the rewards received for it and, on the other, between the contributions and the rewards of relevant other persons in a similar work situation. The choice of the person or group of comparison increases the complexity of the theory. It is an important variable because it can be a person or group within or outside the present organization. As a result, the employee may also compare himself or herself with friends or colleagues in other organizations or from former employments. The choice of the referent is influenced predominantly by information that the employee has about the respective person as well as by the attractiveness of this person. The pertinent research has therefore been interested particularly in the following moderating variables:

- *Gender*. Usually, a person of the same gender is preferred.
- *Duration of Membership in a Company*. The longer the duration of membership, the more frequently a colleague in the same company is preferred.
- *Organizational Level and Training*. The higher the level and the more training a person has, the more likely he or she is to make comparisons with persons outside the organization.

For employees the principle of equity at the workplace is kept when they perceive the ratio of their own contributions (input = $I$) and the rewards obtained (outcome = $O$) as being equivalent to the respective ratio of other persons in the same work situation. Inequity and therefore tension exist for a person when these two ratios are not equivalent. Hence, if this ratio of contribution and reward is smaller or greater for a person than for the referent, the person is motivated to reduce the internal tension produced; one will count as one's contributions everything that one adds personally to a given work situation: psychomotoric or intellectual skills, expertise, traits, or experience. Accordingly, everything that a person obtains and considers as valuable is counted as a reward: remuneration, commendation, appreciation, or promotion. The inner tension perceived by a person pushes for the reestablishment of equity and therefore justice. According to Adams, the strength of the motivated behavior is directly proportional to the amount or strength of tension produced by inequity. Depending on the causes and the strength of the perceived inequity, the person can now choose different alternatives of action that can be predicted by means of the referent. For example, a person can try to get a raise in reward if this is lower than that of the referent chosen. On the other hand, one could increase or decrease one's input by intensifying or reducing one's contributions. If in the case of a perceived inequity neither of these reactions is possible, the person's reaction might be frequent absenteeism from the workplace or even quitting the job. Besides, there are other options as to how to respond: (1) distortion of self-perception, (2) distortion of the perception of others, or (3) variation of the chosen referent.

It is important to state that the contributions as well as the estimation of the rewards and the ratio of the two variables are subject to the perception and judgment of the employee (i.e., they do not necessarily correspond to reality). The majority of research studies on the evaluation of Adams's motivation theory have dealt with the choice of the referent and with payment as a category of reward in work organizations (Husemann et al., 1987; Greenberg, 1988; Summers and DeNisi, 1990; Kulik and Ambrose, 1992). Usually, in these studies for the assessment of the effect of a state of unequal payment in laboratory experiments as well as in field studies, four different conditions have been created: (1) overpayment of the hourly wage, (2) underpayment of the hourly wage, (3) overpayment of the piece wage, and (4) underpayment of the piece wage.

Subjects were assigned in a randomized way to these conditions of inequity, dissonance, and tension. Thus, an employee working under the condition of overpayment/piece wage (i.e., perception of inequity) will improve the quality and reduce the quantity in order to reduce the state of tension because another increase in quantity would augment the state of inequity. In many surveys it turned out to be problematic that the results generally verify the model only under conditions of overpayment and of hourly wage. However, the model could not be supported convincingly concerning overpayment and piece wage (Steers et al., 1996). Moreover, the question of how a person chooses the referent is largely unsolved: whether a person is chosen

within or outside the company and whether the referent is exchanged over the years. Furthermore, there is little knowledge about the strategy of the reduction of tension chosen. Because of a lack of research in this area, it is not yet possible to generalize the applicability of the equity theory with regard to the effect of non-financial rewards. Finally, it seems as if the model's predictable and expectable possibilities to react to solve the problem of inequity that a person can choose from are too limited. Despite these limitations, Adams's motivation model offers the option of explaining and predicting attitudes and reactions of employees (job satisfaction, quitting the job, or absenteeism) on the basis of their rewards and contributions.

### 3.2.4 Locke's Goal-Setting Theory

Locke (1968) holds the view that the conscious goals and aims of persons are the essential cognitive determinants of their behavior. Thereby, values and value judgments play an important role. Humans strive for achievement of their goals to satisfy their emotions and desires. Goals give direction to human behavior, and they guide thoughts and actions. The effect of such goal-setting processes is seen primarily in the fact that they (1) guide attention and action, (2) mobilize effort, (3) increase perseverance, and (4) facilitate the search for adequate strategies of action.

Meanwhile, the goal-setting theory (Figure 7) has attracted wide interest among theorists and practitioners and has received convincing and sustained support by recent research (Tubbs, 1986; Mento et al., 1987). Locke and Latham (1990) point to almost 400 studies dealing solely with the aspect of the difficulty of goals. Through increasing insights into the effect of goal setting on work performance, the original model could be widened.

In organizational psychology, goals serve two different purposes under a motivational perspective: (1) They are set jointly by employees and superiors to serve as a motivational general agreement and mark of orientation that can be aimed at and (2) they can serve as an instrument of control and mechanism of leadership to reach the overall goal of the organization with the help of employees' individual goals.

According to Locke, from a motivational perspective, a goal is something desirable that has to be obtained. As a result, the original theory of 1968 postulates that work performance is determined by two specific factors: the difficulty and specificity of the goal. *Difficulty of the goal* relates to the degree to which a goal represents a challenge and requires an effort. Thereby, to work as an incentive, the goal has to be realistic and achievable. The correctness of this assumption has already been proven by a large number of early studies (Latham and Baldes, 1975; Latham and Yukl, 1975). Locke postulates that the performance of a person can be increased in proportion to the increase in the goal's difficulty until performance reaches a maximum level. *Specificity of goal determination* refers to the degree of distinctness and accuracy with which a goal is set. Correspondingly, the goals to give one's best or to increase productivity are not very specific, whereas the goal to increase turnover by 4% during the next six months is very specific. Goals referring to a certain output or profit or to a reduction in costs are easy to specify. In contrast, goals concerning ethical or social problems and their improvement, such as job satisfaction, organizational culture, image, or working atmosphere, are difficult to grasp in exact terms (Latham and Yukl, 1975).

Set goals do not always result directly in actions but can exist within the person over a longer period of time without a perceivable effect. To become effective, a commitment of the person toward such goals is necessary. The greater the commitment (i.e., the greater the wish to achieve the goal), the more intensive and persistent the person's performance will be influenced by it. It facilitates concentration on action processes and at the same time insulates the person from distractions by potential disturbing variables (e.g., alternative goals). Today, there is abundant research pointing to an extension of the model that would make it possible to meet the complexity of the motivational process concerning setting goals in organizations (Locke and Latham, 1990). A newer version of the theory states that goal-oriented effort is a function not only of the difficulty and specificity of the goal but also of two other goal properties: acceptance and commitment. *Acceptance* refers to the degree to which one views a goal as one's

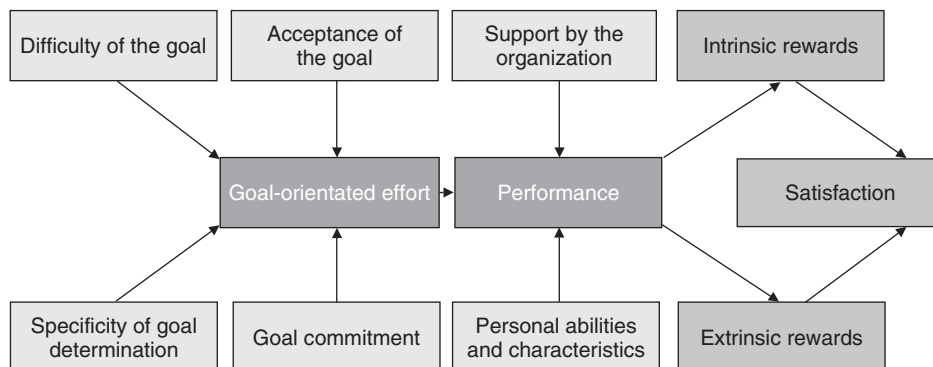

**Figure 7**  Locke's goal-setting theory.

own; *commitment* says something about the degree to which an employee or a superior is personally interested in achieving a goal. Tubbs (1993) pointed out that factors such as active participation while setting goals, challenging at the same time realistic goals, or the certainty that the achievement of the goal will lead to the personally appreciated rewards particularly facilitate goal acceptance and commitment (Kristof, 1996).

The model is being enhanced and improved continuously (Mento et al., 1992; Wofford et al., 1992; Tubbs et al., 1993; Austin and Klein, 1996). The latest developments analyze particularly the role of expectancies, including the differentiation pointed out by Bandura between the *outcome expectation* (the expectation that an action will lead to a certain outcome) and the *efficacy expectation* (the expectation that a person is able to conduct the necessary action successfully) (Bandura, 1982, 1989).

Four central insights are relevant for the practice of organizational psychology in particular:

1. Specific goals (e.g., quotas, marks, or exact numbers) are more effective than vague and general goals (e.g., do your best).

2. Difficult, challenging goals are more effective than relatively easy and common goals. Such goals have to be reachable, though; otherwise, they have a frustrating effect.

3. Accepted goals set in participation are to be preferred over assigned goals.

4. Objective feedback about the advances attained in respect to the goal is absolutely necessary but is not a sufficient condition for the successful implementation of goal setting.

Goal setting offers a useful and important method to motivate employees and junior managers to achieve their goals. These persons will work toward their set goals in a motivated way as long as these are defined exactly and are of a medium difficulty, if they are accepted by employees, and if they show themselves committed to the set goals. The correctness of the assumptions of the theory has been tested in a variety of situations. It turns out that the variables "difficulty" and "specificity" of the goal stand in close relation to performance. Other elements of the theory, such as goal acceptance or commitment, have not been examined that often. Besides, there is little knowledge about how humans accept their goals and how they develop a commitment to certain goals. The question of whether this is a real theory or simply represents an effective technique of motivation has been discussed many times. It has been argued that the process of setting goals constitutes too narrow and rigid a perspective on the employee's behavior. Moreover, it is essential to state that important aspects cannot be quantified that easily. Additionally, goal setting may focus attention on short-term goals, leading to a detriment of long-term considerations. Furthermore, there are other critical appraisals of the theory of goal setting as a motivational instrument of organizational psychology. Setting difficult goals may lead to a higher probability that managers and employees will develop a higher tendency toward risk, which could possibly be counterproductive. In addition, difficult goals can cause stress. Other working areas for which no goals were set might be neglected, and in extreme cases, goal setting may lead to dishonesty and deception.

A practical application of the goal-setting theory is benchmarking. *Benchmarking* refers to the process of comparing the working and/or service processes of one's own company to the best types of processing and production and the results that are detectable in this branch of business. The objective is to identify necessary changes to improve the quality of one's own products and services. The technique of goal setting is used to initiate the necessary activities, to identify the goals that have to be pursued, and to use these as a basis of future actions. To improve one's own work, production, and fabrication, not only the processes within but also those outside the organization are inspected. Through this procedure, several advantages emerge for the company: (1) Benchmarking enables the company to learn from others, (2) the technique places the company in a position to compare itself with a successful competitor, with the objective of identifying strategies of improvement, and (3) benchmarking helps to make a need for change visible in the company by showing how one's own procedures and the assignment of tasks have to be changed and how resources have to be reallocated.

A broader perspective of goal setting in terms of a motivational function is the process of *management by objectives* (MBO). The term refers to a joint process of setting goals with the participation of subordinates and superiors in a company; by doing this, the company's objectives circulate and are communicated top down (Rodgers et al., 1993). Today, MBO is a widespread technique of leadership and motivation featuring substantial advantages: MBO (1) possesses a good potential for motivation, helping to implement the theory of goal setting systematically into the organizational process of a company, (2) stimulates communication, (3) clarifies the system of rewards, (4) simplifies performance review, and (5) can serve managers as a controlling instrument.

Although the technique has to be adjusted to the specific needs and circumstances of the company, there is a general way of proceeding. Top management has to draw up the global objectives of the company and has to stand personally for implementation of the MBO program. After top management has set these goals and has communicated them to the members of the company, superiors and the respective assigned or subordinate employees have to decide jointly on appropriate objectives. Thereby, each superior meets with each employee and communicates the corresponding goals of the division or department. Both have to determine how the employee can contribute to the achievement of these goals in the most effective way. Here, the superior works as a consultant to ensure that the employee sets realistic and challenging goals that are at the same time exactly measurable and verifiable. Finally, it has to be ensured that all resources the employee needs for the achievement of the goals are available. Usually, there are four

basic components of a MBO model: (1) exact description of the objective, (2) participation in the decision making, (3) an explicit period of time, and (4) feedback on the work performed.

Generally, the time frame set for achievement of the objectives is one year. During this period the superior meets on a regular basis with each employee to check progress. It can turn out that because of new information, goals have to be modified or additional resources are necessary. At the end of the set time frame, each superior meets with each employee for a final appraisal conversation to assess to what degree the goals have been reached and the reasons for this conclusion. Such a meeting also serves to revise the proposed figures and performance levels, to determine changes in payment, and as a starting session for a new MBO cycle in the following year.

Overall, goal-setting theory can be considered as being confirmed rather well for individual behavior (Kleinbeck et al., 1990), while its effect on groups or even entire organizations seems to depend on additional conditions that are not yet clarified sufficiently (Miner, 1980). Results are showing that goal setting works better if linked to information about reasonable strategies of action and that both goal setting and strategic information facilitate effort as well as planning behavior (Earley et al., 1987). Moreover, it has to be stressed that the achievement of goals can itself be motivating (Bandura, 1989). Here the thesis of Hacker (1986) is confirmed, stating that tasks not only are directed by motives but also can modify motives and needs.

### 3.2.5 Kelley's Attribution Theory

Research about behavior in organizations has shown that attributions made by managers and employees provide very useful explanations for work motivation. Thus, the theory of attribution (Myers, 1990; Stroebe et al., 1997) offers a better understanding of human behavior in organizations. It is important to point out that, in contrast to other motivation theories, the theory of attribution is, rather, a theory of the relation between personal perception and interpersonal behavior.

As one of the main representatives of this direction of research, Kelley (1967) emphasizes that attribution theory deals with the cognitive processes with which a person interprets behavior as caused by the environment or by characteristics of the actor. Attribution theory mainly asks questions about the "why" of motivation and behavior. Apparently, most causes for human behavior are not observable directly. For this reason, one has to rely on cognitions, especially on perception. Kelley postulates that humans are rational and motivated to identify and understand structures of reasons in their relevant environment. Hence, the main characteristic of attribution theory consists in the search for attributions. At present, one of the most frequently used attributions in organizational psychology is the locus of control. By means of the dimension internal/external, it can be explained whether an employee views his or her work outcome as dependent on either internal or external control (i.e., whether the employee considers himself or herself as able to influence the result personally, e.g.,

through his or her skills and effort, or thinks that the result lies beyond his or her own possibilities of influence and control). It is therefore important that this perceived locus of control has an effect on the performance and satisfaction of the employee. Research studies by Spector (1982) and Kren (1992) point to a correlation of the locus of control and work performance and job satisfaction that is not only statistical in nature. Concerning the relation between motivation and work incentives, it also seems to take a moderating position. Despite the fact that until now the locus of the control dimensions internality and externality for the explanation of work motivation has been the only link on the part of organizational psychology to the attributional approach, it has been suggested repeatedly that other dimensions be examined as well. Weiner (1985) proposes a dimension of stability (fixed vs. variable, e.g., in terms of the stability of internal attribution concerning one's own abilities).

Kelley suggests the dimensions consensus (refers to persons: do others act similarly in this situation?), distinctiveness (refers to tasks: does the person act on this task as on other tasks?), and consistency (refers to time: does the person always act in the same way over time?). These dimensions will influence the type of attribution that is made, for example, by a superior (Kelley, 1973). If consensus, consistency, and distinctiveness are high, the superior will attribute the working behavior of an employee to external (i.e., situational or environmental) causes (e.g., the task cannot be fulfilled better because of external circumstances). If consensus is low, consistency high, and distinctiveness low, causes are attributed to internal or personal factors (e.g., the employee lacks skills, effort, or motivation) (Mitchell and Wood, 1980).

The attributional approach offers promising possibilities for organizational psychology to explain work behavior. However, it has to be mentioned that various sources of error have to be taken into account. For example, there is an obvious tendency of managers to attribute situational difficulties to personal factors (skills, motivation, attitudes). But the reverse also occurs quite frequently: In too many cases, failure is attributed to external factors although personal factors are actually responsible.

### 3.2.6 Summary of Process Models

Process theories refer more closely to actual behavior; they take into account connections between appraisals and results and thereby fill a gap left open by the content theories. Moreover, they do not assume that all people are led by the same motives but emphasize, instead, that each person can have his or her own configuration of desired and undesired facts. They thus open a perspective toward conflicting motives; they can explain why a highly valued behavior might not be executed (e.g., because another one is valued even more or because the expectation to be successful is too small); to the tempting tendency to presume human motives, they oppose the demand not to assume but to study these; and they point out processes that support the connection of highly valued facts and concrete actions (e.g., goal setting, feedback, clear presentation of consequences).

Nevertheless, the question remains unanswered as to what typically is valued as high by which persons—hence, the issue of the contents cannot be evaded. And these are, despite big differences between persons, not so arbitrary that there is nothing that could be said about them. Therefore, the great strength of not assuming any contents becomes a weakness as well. Nevertheless, process models have received a lot of support and they have practical implications. But concerning the contents, not everything should be set aside unseen.

Ultimately, the two approaches deal with completely different aspects. The link between basic motives and specific actions is manifold and indirect, influenced by lots of aspects (e.g., expectations, abilities, situational restrictions); that is why a close direct relationship cannot be expected. To consider the contents (which do not differ much in the various approaches) as usually being effective without presuming them stiffly for each person and to take into account at the same time, the characteristics specified by the process models can provide guidance for practice and theoretical integration possibilities that seem already to have emerged (Locke and Henne, 1986; Six and Kleinbeck, 1989).

### 3.2.7   Recent Developments in Theories of Work Motivation

In the past five years a "revolutionary" new theory of work motivation with practical impact cannot be discovered in the literature. However, under the influence of the management literature, the discussion shifts in focus from the more person-centered view to the more situation-centered view to find, for example, empirical evidence for situations that can be considered as hindering goal-oriented performance items in different elements of the performance picture (Brandstätter and Schnelle, 2007; Nerdinger et al., 2008). The content models are stable in discussion of the "universal" motives but are "unlimited" in the development of motivation factors specified for certain groups and purposes. The process models seem to develop more and more into a section of cognitive theories of goal choice and a section of volitional theories of goal realization. However, both rely on action regulation principles (Nerdinger, 2006; Heckhausen and Heckhausen, 2006).

### 4   POSSIBLE APPLICATIONS OF MOTIVATION MODELS

A question arises as to ways in which the theories of motivation can be applied to the world of work. All of these models can contribute in different ways to a better understanding and predetermination of human behavior and reactions in organizations. This has already been proven for each model. In the following sections we examine the possible applications more closely: involvement and empowerment, remuneration, work and task design, working time, and motivation of various target groups.

### 4.1   Involvement and Empowerment

The role of involvement and empowerment as motivational processes can be seen with regard to need-oriented actions as well as with regard to the postulates of the expectancy theory of motivation. Employee involvement is creating an environment in which people have an impact on decisions and actions that affect their jobs (Argyris, 2001). Employee involvement is neither the goal nor a tool as practiced in many organizations. Rather, it is a management and leadership philosophy about how people are most enabled to contribute to continuous improvement and the ongoing success of their work organization. One form of involvement is *empowerment*, the process of enabling or authorizing a person to think, behave, take action, and control work and decision making in autonomous ways. It is the state of feeling empowered to take control of one's own destiny. Thus, empowerment is a broad concept that aims at reaching involvement in a whole array of different areas of occupation.

Empowerment does not primarily use involvement to reach higher satisfaction and to increase personal performance. The vital point within this process is, rather, the overall contribution of human resources to the efficiency of a company. Employees who can participate in the decision-making process show higher commitment when carrying out these decisions. This addresses simultaneously the two factors in the need for achievement: The person feels appreciated and accepted, and responsibility and self-esteem are increasing.

Furthermore, involvement in decision making helps to clear up expectations and to make the connection between performance and compensation more transparent. Involvement and empowerment can be implemented in various fields, which may concern work itself (e.g., execution, tools, material) or administrative processes (e.g., work planning). Moreover, involvement means participation in relevant decisions concerning the entire company. Naturally, the underlying idea is that employees who are involved in decisions have a considerable impact on their work life, and workers who have more control and autonomy over their work life are motivated to a higher extent, are more productive, and are more satisfied with their work and will thus show higher commitment.

Organizations have experimented for years with lots of different techniques to stimulate involvement and empowerment among their employees and executives.

Quality circles as an integrative approach have attracted particular attention. Their task is to solve work problems with the help of regular discussions among a number of employees. In connection with quality management and qualification programs, quality circles play a crucial role in learning organizations. Not only do they make possible a continuous improvement process and an ideal integration of the experiences of every employee, but they also allow participants to acquire various technical skills and social competences.

To ensure these positive effects, it is crucial that quality circles not pursue solely economic goals. Specific needs and requests of employees regarding improvements in job quality or humanization of work must be

considered equally. However, the evidence is somehow restricted. Although a lot of organizations say that quality circles lead to positive results, there is little research about long-term efficiency (Griffin, 1988).

Another commonly used method of involvement and empowerment of employees is that of work teams. These can be, for example, committees, cross-functional work teams, or interfunctional management teams. They comprise representatives of different departments (e.g., finance, marketing, production) that work together on various projects and activities (e.g., launch of a new product) (Saavedra et al., 1993).

## 4.2   Remuneration

The issue of financial compensation for both executives and employees plays a crucial role in practice (Ash et al., 1985; Judge and Welbourne, 1994; Schettgen, 1996). According to Maslow, payment satisfies the lower needs (physiological and safety needs), and Herzberg considers it as one of the hygienes. Vroom regards payment as a result of the second level that is of particular valence for the employee. According to his VIE theory, the resulting commitment will be high when work leads to a result and a reward highly appreciated by the employee. Adams's equity theory puts emphasis on the relation between commitment and return of work performance. This input/output relation is correlated with a comparison person called a *referent*, a comparison position, or a comparison profession. Perceived inequality leads to attempts at its reduction by changing work commitment or return. Perceived underpayment has, therefore, a negative impact on performance in terms of quality as well as quantity.

The same applies to fringe benefits such as promotions or job security. Three different factors are to be considered which determine the efficiency of payment schemes with regard to the theories of motivation mentioned above: (1) the type of relation between the payment scheme and a person's work performance, (2) the subjective perception of these connections, and (3) different assessments of payment schemes by employees in the same work situation. In addition to that, there are internal performance-oriented benefits, staff shares, and employee suggestion schemes either within or outside the department. Eventually, various additional premiums, such as an increased Christmas bonus or a company pension, have to be mentioned; the latter, especially, is a vital factor in times of diminishing governmental provision.

## 4.3   Work Design

The way in which tasks are combined, the degree of flexibility that executives and employees have, and the existence or lack of important support systems in a company have a direct impact on motivation and on work performance and satisfaction. Motives can be generated within a job by extending work contents and demands.

Organizational psychological research since the 1960s has shown repeatedly that a certain task complexity positively affects work behavior and lots of employees prefer jobs that contain complexity and challenge. But taking a closer look at the actual development of work tasks, one has to conclude that the results noted above have, due largely to economic considerations, generally been ignored, and most work flows have been organized on the basis of economic and technical efficiency. They were primarily attempts to create very specialized work roles and control employees. However, the situation today has changed significantly.

Executives have acknowledged that the most valuable resource available is employee commitment, motivation, and creativity. Only this lets a company stay healthy and competitive in global markets. Technology and downsizing alone can achieve neither flexibility nor new, customer-oriented products and services. It is motivation that must be improved. This can be realized partially by restructuring work tasks and working processes.

### 4.3.1   Strategies of Work Design

**Corrective Work Design**   It is a widespread experience that working systems and work flows have to be changed after their introduction into a company in order to adapt them to specific human needs. Often, these corrections are necessary because of insufficient consideration of anthropometric or ergonomic demands. Such procedures, called *corrective work design*, are always necessary when ergonomic, physiological, psychological, safety–technical, or judicial requirements are not (or not sufficiently) met by planners, design engineers, machine producers, software engineers, organizers, and other responsible authorities. Corrective work design that is at least somewhat effective often causes considerable economic costs. However, its omission can potentially cause physical, psychophysical, or psychosocial harm. Expenditures on corrective work design have to be borne by the companies, whereas the latter costs are carried by the employees affected and thus indirectly by the economy. Both types of costs can be avoided or at least reduced considerably if corrective work design is replaced as far as possible by preventive work design.

**Preventive Work Design**   Preventive work design means that concepts and rules of work science are considered when working systems and work flows are being developed. Hence, possible damage to health and well-being are taken into account when job division between humans and machines is being determined.

**Prospective Work Design**   The strategy of prospective work design arises due to the demand for personality-developing jobs. The criterion of personality development puts an emphasis on the fact that the adult personality develops mainly by dealing with its job. Jobs and working conditions that are personality developing ensure that a person's characteristic strengths can be kept and further developed. Prospective work design means that possibilities of personal development are created intentionally at the stage of planning or reengineering of work systems. This is done by creating a scope of action that can be used and, if possible, extended by employees in different ways. It is crucial for the strategy of prospective work design not to regard it as equivalent to future-oriented work design. Instead, the creation

of work that provides possibilities of development for employees should be seen as a vital feature.

***Differential Work Design***   The principle of differential work design (Ulich, 1990, 1991) takes into account differences between employees: that is, it considers interindividual differences (e.g., different working styles) in dealing with jobs. Employees can choose between different work structures according to their individual preferences and abilities. Since human beings develop through dealing with their jobs, changes among work structures and altering of the structures should be made possible.

The possibility of choosing among alternatives and of correcting a choice, if necessary, means that there will be no need to look for the one best way of organizing jobs and work flows. However, this implies a considerable increase in autonomy and control over one's working conditions. Furthermore, such possibilities of job change lead to a reduction in unbalanced strains.

***Dynamic Work Design***   Dynamic work design does not mean a choice between different existing structures but deals with the possibility of continuously changing and extending existing work structures and creating new ones. Dynamic work design takes into account intraindividual differences (e.g., different learning experiences) in dealing with jobs.

***Empirical Evidence Concerning Differential and Dynamic Work Design***   Without considering interindividual differences, neither optimal personal development nor optimal efficiency can be guaranteed. Differences in cognitive complexity and memory organization may play a role that is just as important as differences in the degree of anticipation, the motivational orientation, the style of learning, or the style of information processing. Empirical data support the assumption that the concept of the one best way, which only needs to be found, constitutes a fundamental and far-reaching error of traditional work design. Moreover, it becomes clear that a standard job structure that is optimal for every employee cannot exist (Zink, 1978). This is consistent with Triebe's (1980, 1981) investigations: In the absence of detailed work schedules, there are interindividually different possibilities as to how to assemble car engines. He observed that workers developed a whole array of different strategies and that these by no means necessarily lead to differing efficiency or effectiveness. Conversely, such results mean that strict work schedules for an operating sequence, which are supposed to be optimal, may sometimes even lead to inefficient work. Differential work design stands out deliberately against the classic search for the one best way in designing work flows. Considering interindividual differences, it is especially appropriate to offer alternative work structures to guarantee optimal personal development in the job.

To take into account processes of personal development (i.e., intraindividual differences in time), the principle of differential work design must be complemented by the principle of dynamic work design. Steinmann and Schreyögg (1980) have pointed out that, when facing choices, some employees might choose the conventional working conditions they are used to. These employees have developed a resigned general attitude and a state of more or less apathetic helplessness because of unchallenging tasks and missing prospects. Hence, it is necessary to develop procedures that make it possible to emphasize a worker's subject position, to reduce barriers to qualification, and to promote readiness for qualification (Alioth, 1980; Ulich, 1981; Baitsch, 1985; Duell and Frei, 1986).

More generally, differential work design can form a link between work design measures, different conditions, and needs of individuals.

It is an important principle of modern work design to offer different work structures. Zülch and Starringer (1984) describe its realization in business by examining the production of electronic flat modules. A macro–work system was created in which differently skilled and motivated employees were simultaneously offered different forms of work organization with different work items. The authors conclude that these new work structures were seen as interesting and motivating.

According to Grob (1985), who provides data and hints for possible extensions, this structure can be applied not only to the production of flat modules but also to all jobs in the company that (1) require several (normally 4–10) employees, (2) have to be carried out frequently in different types and variants, (3) have to be managed with few workshop supplies, and (4) may have a crucial impact on reducing the duration of the cycle time. In this context it is especially important that Zülch and Starringer (1984) were able to prove theoretically that the concept of differential work design can even be realized when facing progressing automation. The production of electronic flat modules for communication devices can serve as an example. It turned out that a useful division into automatic and human operations can be facilitated by not automating all possible operations.

In the beginning, interindividual differences concerning the interaction between individuals and computers were examined almost entirely with regard to the user's role as beginner, advanced user, or expert when dealing with technical systems. It became more and more obvious, however, that the impact of differential concepts goes far beyond that. Hence, Paetau and Pieper (1985) report, with reference to the concept of differential work design, laboratory experiments that examined whether test subjects with approximately the same skills and experiences and given the same work items develop the same preferences for certain systems. Given various office applications, individuals at first preferred a high degree of menu prompting. But with increasing experience, accordance in preferences declined significantly. Due to their results and the experiences and concepts of other authors, Paetau and Pieper (1985) do not see any point in looking for an optimal dialogue design. Demands for programmable software systems, flexible information systems, adaptability of groupware, adaptability of user interfaces, or choices between alternative forms of dialogue put emphasis on the necessary consideration of inter- and intraindividual differences by means of differential and dynamic work design. This has been reflected in the European Community (EC) guideline

90/270/EWG and in International Organization for Standardization (ISO) 9241 (Haaks, 1992; Oberquelle, 1993; Rauterberg et al., 1994). Triebe et al. (1987) conclude that creating possibilities for individualization with the help of individually adaptable user interfaces will probably be one of the most important means of optimizing strain, preventing stress, and developing personality.

Possible achievements and results of the creation of these scopes of development have mainly been examined experimentally. Results of these studies (e.g., Ackermann and Ulich, 1987; Greif and Gediga, 1987; Morrison and Noble, 1987) support the postulate of abolishing generalizing one-best-way concepts in favor of differential work design. Both the participative development of scopes for action and the possible choice between different job structures will objectively increase control in the sense of being able to influence relevant working conditions. This shows at the same time that possibilities of individualization and differential work design are determined at the stage of software development. This is similar for production, where the scope for action is determined mainly by design engineers and planners. Interindividually differing proceedings also matter in design engineers' work. This is revealed in a study by von der Weth (1988) examining the application of concepts and methods of psychological problem solving in design engineering. Design engineers, who acted as test subjects, had to solve a construction task while thinking aloud. Their behavior was registered by video cameras. One of the results that applies to this context says that test persons with adequate problem-solving skills do not show homogeneous procedures. Both the strategy of putting a draft gradually into concrete terms as well as joining solutions of single detailed problems together into a total solution led to success. Thus, the author concludes that an optimal way of reaching a solution that is equally efficient for everybody does not exist. He assumes that this is caused by different styles of behavior which are linked to motivational components such as control needs. As a conclusion, design engineers must be offered a whole array of visual and linguistic possibilities for presenting and linking information. If the system forces a special procedure on users, a lot of creative potential is lost.

***Participative Work Design*** Another strategy, participative work design, has to be considered (Ulich, 1981). In participative work design, all persons concerned with work design measures are included. This participation must focus on all stages of a measure (e.g., including preliminary activities such as evaluation of the actual situation). Participative work design must not result in participation of persons concerned only when one is stuck (e.g., due to technical problems). It must not be a pure measure to get decisions accepted. The various principles overlap and thus cannot often be identified unequivocally. Different strategies of work design pursue different goals that differ not only qualitatively but also in terms of range and time horizon (Ulich, 1980).

The design of work structures implies change in technical, organizational, and social working conditions to adapt structures to workers' qualifications. In this way, they aim at promoting personality development and well-being of workers within the scope of efficient and productive work flows. Criteria are needed to assess jobs and the related design measures concerning this aim. Work psychology and work science can provide a large number of findings and offer support for this (e.g., Oppolzer, 1989; Greif et al., 1991; Leitner, 1993).

### 4.3.2 Characteristics of Task Design

From the point of view of industrial psychology, task design can be seen as an interface between technical or organizational demands and human capabilities (Volpert, 1987). As a consequence, work content and work routine will be determined fundamentally by the design of tasks. Therefore, task design plays a key role in effectiveness, work load, and personality development. Hence, task design takes precedence over the design of work materials and technology, since their use is determined fundamentally by work content and work routine.

Task analysis methods can be used to improve task design. Luczak (1997, p. 341) sees the fundamental idea of task analysis "in a science-based and purpose-oriented method or procedure to determine, what kind of elements the respective task is composed of, how these elements are arranged and structured in a logical or/and timely order, how the existence of a task can be explained or justified ... and how the task or its elements can be aggregated to another entity, composition or compound." Their aim is to transform the task into complete activities or actions.

***Design Criteria*** Tasks should be workable, harmless, and free of impairment and sustain the development of the working person's personality (Luczak et al., 2003). The fundamental aim of task design is to abolish the Tayloristic separation of preparing, planning, performing, and controlling activities (Locke, 2003) so as to make complete activities or actions possible (Hacker, 1986; Volpert, 1987). The results are tasks that offer goal-setting possibilities, the choice between different work modes, and the control of work results. Essentially, it is about granting people a certain scope in decision making.

The attempt in sociotechnical system design (e.g., Alioth, 1980; Trist, 1990) to name other design criteria can be seen as important for the development of abilities and motivation (Ulich, 1993). In addition to the aforementioned autonomy, these are (1) completeness of a task, (2) skill variety, (3) possibilities of social interaction, (4) room for decision making, and (5) possibilities of learning and development. Tasks designed according to these guidelines promote employee motivation, qualifications, and flexibility and are therefore an excellent way to provide and promote the personnel resources of a company in a sensible and economical manner.

Similar dimensions can also be found in the *job characteristics model* of Hackman and Oldham (1976). In the concept of *human strong points* (Dunckel et al., 1993), these criteria are taken up and widened. Human criteria for the assessment and design of tasks and work systems are formulated: (1) Work tasks should have a wide scope concerning actions, decisions, and

time; (2) the working conditions and especially the technology should be easily comprehensible and changeable in accordance with one's own aims; (3) task fulfillment should not be hindered by organizational or technical conditions; (4) the work tasks should require sufficient physical activity; (5) the work tasks should enable dealing with real objects and/or direct access to social situations; (6) human work tasks should offer possibilities for variation; and (7) human work tasks should enable and promote social cooperation as well as direct interpersonal contacts.

According to the definition of work science (Luczak et al., 1989), human criteria are only one theoretically justified way for the assessment and design of work under human aspects (Dunckel, 1996). Neuberger (1985), for example, names other aims of humanization, such as dignity, meaning, security, and beauty. It has to be considered that personality-supporting task design also has a positive effect on the use of technology and on customer orientation; in addition to that, it promises clear economic benefits (Landau et al., 2003). Furthermore, it is interesting to know how work tasks should be designed to create task orientation. Task orientation promotes the development of personality in the process of work and motivates employees to perform tasks without requiring permanent compensation and stimulation from the outside.

***Task Orientation***   Task orientation describes a state of interest and commitment that is created by certain characteristics of the task. Emery (1959) names two conditions for the creation of task orientation: (1) The working person must have the control over the work process and the equipment needed for it and (2) the structural characteristics of a task need to be of a type that sets off in the working person the strength for completing or continuing the work. The extent of control over the work process depends not only on the characteristics of the task or the delegated authority but also, above all, on the knowledge and competence that are brought into dealing with a task.

For those motivational powers that have a stimulating effect on completing or continuing the work, the task itself has to appear to be a challenge with realistic demands (Alioth, 1980). Apart from that, it should be neither too simple nor too complex. Summing up the statements of Emery and Emery (1974), Cherns (1976), and Emery and Thorsrud (1976), the following characteristics of work tasks encourage the process of a task orientation: completeness, skill variety, possibilities for social interaction, autonomy, and possibilities for learning and development. Furthermore, Emery and Thorsrud mention the aspect of meaning. Therefore, work should make a visible contribution to the usefulness of a product for the consumer.

These characteristics correspond so well with the characteristics of tasks derived theoretically by Hackman and Lawler (1971) and Hackman and Oldham (1976) that Trist (1981) points out that this degree of agreement is exceptional in such a new field and has placed work redesign on a firmer foundation than is commonly realized.

***Task Completeness***   An early description of what is now called a *complete task* can be found in Hellpach's article about group fabrication (Hellpach, 1922). He came to the conclusion that it should be a main objective to overcome fragmentation in favor of complete tasks, in the sense of the at least partial restoration of the unity of planning, performing, and controlling. Incomplete tasks show a lack of possibilities for individual goal setting and decision making, for the development of individual working methods, or for sufficiently exact feedback (Hacker, 1987). Research could show, furthermore, that the fragmentation that goes together with classic rationalization strategy can have negative effects on a person in many areas. Restrictions on the scope of action can lead to indisposition and to continuous mental and physical problems. It can also possibly result in the reduction of individual efficiency, especially of mental activity, and passive leisure behavior, as well as in a lower commitment in the areas of politics and trade unions.

Specific consequences for production design resulting from the principle of the complete task may be outlined at this point with the help of some examples:

1.  The independent setting of aims requires a turning away from central control to decentralized workshop control; this creates the possibility of individual decision making within defined periods of time.
2.  Individual preparations for actions require the integration of planning tasks into the workshop.
3.  Choice of equipment can mean, for example, leaving to the constructor the decision of using a drawing board (or forming models by hand) instead of using computer-aided design for the execution of certain construction tasks.
4.  Isolated working processes require feedback as to progress, to minimize the distance and to make corrections possible.
5.  Control with feedback as to the results means transferring the functions of quality control to the workshop itself.

First, a complete task is complete in a sequential sense. Besides mere execution functions, it contains preparation functions (goal setting, development of the way of processing, choosing useful variations in the work mode), coordination functions (divide the tasks among a variety of people), and control functions (get feedback about the achievement of the goals set). Second, complete tasks are complete in a hierarchical regard. They make demands on different alternating levels of work regulation. It should be noted that complete tasks, because of their complexity, can often be designed only as group tasks.

***Job Enrichment***   *Job enrichment* is commonly described as changes regarding the content of an employee's work process. Herzberg (1968) points out that, with the help of this method, motivation is being integrated into an employee's work process to improve

his or her satisfaction and performance. Job enrichment refers to the *vertical* widening of a work role. The aim is to give employees more control concerning planning, performing, and appraisal of their work. Tasks will be organized such that they appear to be a complete module to heighten identity with the task and to create greater variety. Work is to be experienced as meaningful, interesting, and important. Employees will receive more independence, freedom, and heightened responsibility. On top of that, employees will get regular feedback, enabling them to assess their own performance and, if necessary, to adjust it. In this context, customer orientation is of special importance. It will result nearly automatically in direct and regular feedback. The customer can be either internal or external, but the relationship must be direct.

Reports from large companies such as Imperial Chemical Industries (Paul et al., 1969) and Texas Instruments (Myers, 1970) tell of the success of job enrichment programs. Ford (1969) mentioned about 19 job enrichment projects from the American Telephone and Telegraph Company; nine were called extraordinarily successful, nine successful, and one a failure. The success was often rated by means of productivity and quality reference numbers, the rate of times absent and of turnover, and examinations of the attitude of employees.

**Job Enlargement**   *Job enlargement* refers to the *horizontal* expansion of a work role. In this process the number and variety of tasks may be increased to diversify and achieve a motivational effect. Employees will perform several operations on the same product or service. Job enlargement therefore intends to string together several equally structured or simple task elements and, by doing that, to enlarge the work cycle. It becomes obvious that job enlargement touches primarily on the work process, whereas an attempt at job enrichment also concerns the organizational structure. However, it is only the realization of concepts of vertical work expansion that can contribute to overcoming the Tayloristic principle of separating planning and performing and therefore to a work arrangement that develops the personality of an employee. On the other hand, research results have shown that outcomes regarding a heightened challenge or motivation have been rather disappointing (Campion and McClelland, 1993).

**Job Rotation**   *Job rotation* deals with lateral exchange of a work role. If a strong routine in the work becomes a problem for employees, if the tasks are no longer challenging, and the employee is no longer motivated, many companies make use of the principle of rotation to avoid boredom. An employee will usually be transferred from one task to another periodically. This principle is also favorable for the company: Employees with a wider span of experience and abilities allow for more flexibility regarding adaptation to change and the filling of vacancies. On the other hand, this process has disadvantages: Job rotation increases the cost of training, employees will always be transferred to a new position when they are on the highest productive level and have thus reached the highest efficiency,

the process can have negative consequences on a well-operating team, and the process can have negative effects on ambitious employees, who would like to take on particular responsibilities in a chosen position.

**Group Tasks**   Currently, companies employ project teams, quality circles, and working groups as typical forms of teamwork. The main task of *project teams* is to solve interdisciplinary problems. Unlike quality circles and working groups, however, they work together for only a limited period of time and will be dissolved after having found the solution to a certain problem (Rosenstiel et al., 1994). The group will therefore be put together on the basis of professional criteria and will consist mostly of employees in middle and upper management. Well-founded evaluations about the concept of project teams are still missing. That is why Bungard et al. (1993) discover a clear deficiency of research, although project teams gain more and more importance in companies.

It is typical of *quality circles* that groups do not work together continuously; instead, they meet only at regular intervals. Employees get the chance to think about improvements systematically. Attendance is explicitly optional (i.e., employees need to wish to deal with these questions). Other requirements for the success of quality circles are a usable infrastructure in the company (e.g., a conference room and moderation equipment); company support, especially from middle management; and a business culture that is characterized by participation and comprehensive quality thoughts. Behind this concept is the idea that the people affected are better able than anyone else to recognize and solve their own problems. As a side effect, communication among employees will also improve (Wiendieck, 1986a,b).

*Working groups* are organizational units that can regulate themselves within defined boundaries. It therefore is a group that is supposed to solve essential problems with sole responsibility. This work form is, among other things, meant to create motivating work contents and working conditions. The concepts of job enlargement, job enrichment, and job rotation are transferred to the group situation (Rosenstiel et al., 1994; Hackman, 2002).

Psychologically, work in a group has two principal intertwined reasons: (1) The experience of a complete task is possible in modern work processes only where interdependent parts are combined to complete group tasks and (2) the combination of interdependent parts to a common group task makes a higher degree of self-regulation and social support possible. Concerning the first point, Wilson and Trist (1951) as well as Rice (1958) found out that in cases in which the individual task does not allow this, satisfaction can result from cooperation in completing a group task. Concerning the second point, Wilson and Trist are of the opinion that the possible degree of group autonomy can be characterized by how far the group task shows an independent and complete unit. Incidentally, Emery (1959) found out that a common work orientation in a group develops only if the group has a common task for which it can take over responsibility as a group and if it is able to control the work process inside the group.

The common and complete task is what practically all supporters of the sociotechnical approach call a central characteristic of group work (Weber and Ulich, 1993). The existence of a common task and task orientation also has an essential influence on the intensity and length of group cohesion. Work groups whose cohesion is based mainly on socioemotional relations therefore show less stability than do work groups that have a common task orientation (Alioth et al., 1976).

Hackman's (1987) considerations about group work make clear that the organization of work in groups contributes not only to the support of work motivation but also to an increase in work efficiency and therefore in productivity. However, work motivation and efficiency will not develop without organizational efforts and will not remain without any kind of endeavor. A study conducted by a German university together with six well-known companies and more than 200 employees revealed that insufficient adaptation of the organization to the requirements of teamwork is the biggest problem area (Windel and Zimolong, 1998). Another problem is that companies at first sight believe that teamwork is a concept of better value compared to the acquisition of expensive technical systems. Windel and Zimolong stress that even with teamwork investments (e.g., into the qualification of employees) are necessary before the concept pays off in the medium and long terms. For the management of a company, this means that in addition to endurance there needs to be trust in the concept.

Teamwork is associated with a variety of dangers for which a company needs to be prepared (e.g., group targets do not orient themselves toward the overall goals of the company). Therefore, systems are needed that are able to develop complete tasks and that can also be used to orient the motivation potentials toward organizational goals. Arbitrarily used scopes of action and motivation potentials can endanger an organization fundamentally. Such instruments need to include the various areas of responsibility and to turn the work of the group into something measurable in order to compare it to the goals set. In addition, it should offer the possibility of assessing the working results of the group regarding their importance for the entire organization and to give feedback to employees. In this way, the productivity of the organization can be increased because at the same time a high work motivation arises. As a consequence, individual preconditions for performance are used optimally, absenteeism decreases, and work satisfaction increases.

### 4.3.3 Working Time

Motivation, satisfaction, absenteeism, and work performance can be improved within certain limits by means of the implementation of alternative models of working time. It is also possible to explain this improvement in terms of the reduction in need deficiencies, the achievement of a second-level result and its instrumentality, the principle of affiliation, or the motivators developed. The model that is being used most frequently is *flextime*. Here the employee has to stick to certain mandatory working hours, beyond which it is up to him or her how the rest of the workday is arranged. Such a model can be expanded such that extra hours can be saved to create a free day each month. The advantages of this popular model are considerable for both sides and range from the reduction of absenteeism to cost saving and higher productivity and satisfaction to increased autonomy and responsibility at the workplace (Ralston and Flanagan, 1985; Ralston et al., 1985). However, there are a lot of professions for which the model is not applicable. *Job sharing* refers to the division of a job or work week between two or more persons. This approach offers a maximum of flexibility for the employees and for the company.

In the search for new work structures, *teleworking* has been a main point of issue for many years. The term refers to employees who do their job at home at a computer that is connected to their office or their company. The tasks range from programming to processing and analysis of data to the acceptance of orders, reservations, and bookings by telephone. The advantages for the employees and the organization are obvious: For the former it means no traveling to and from work and flexible working hours, and for the latter there is an immense reduction in costs. The disadvantages include a lack of important social contacts and sources of information, and because the employee is no longer integrated into important processes, they might suffer from disadvantages concerning promotions and salary increases.

Other models of working time are also being discussed, such as the *compressed workweek*, with the same number of working hours completed in four days of nine hours each. Supporting this approach, it has been argued that there would be extended leisure time and that employees would not have to travel to and from work during rush hour. It has also been stated that with the help of this model commitment, job satisfaction, and productivity would be increased and costs would be reduced. Extra hours would no longer be necessary, and rates of absenteeism would be lower. Undoubtedly, the acceptance of this model among employees is rather high, but there are also opponents of the approach. They consider the workday as being too long and believe that problems will arise in trying to structure the demands of private life with those of the job.

A working time model that seems to be especially beneficial for older employees or to fight high unemployment is a reduction in the weekly working time without pay compensation. For older employees this eases the transition to retirement. In the scope of measures against unemployment, this model would stand for a fairer allocation of existing work to a greater number of people without increasing total costs. However, for employees it is most important how they are affected personally rather than the positive effects that the model has on a country's unemployment problem.

Another solution that is being discussed, especially for large projects where considerable overtime can be necessary, is to give the employee a time account. As soon as the project is finished, he or she can take up to two months off while receiving his or her regular pay.

### 4.3.4 Motivation of Various Target Groups

In an increasingly diversifying working world (Jackson, 1992; Jackson and Ruderman, 1995) individual differences with respect to needs and expectations are wide. On the part of companies, they are hardly taken into account or taken seriously. For this reason, some motivating measures have little effect. This is why organizations of the future will have to strive for more flexibility regarding the structuring of work and work processes. If they want to maintain the commitment, motivation, and creativity of their managers and employees, they will have to consider family-oriented employees as well as dual-career couples. Organizations of the future will have to show just as much interest in fast-trackers pushing early for leadership responsibility as in employees entering a field that is different from their educational background or midcareer persons wanting to take on a completely new profession.

Different needs and values in various professional groups are crucial for whether or not a motivational measure is effective. In academic professions, especially, employees and managers obtain a considerable part of their intrinsic satisfaction out of their job. They have a very strong and long-lasting commitment toward their field of work, and their loyalty to their special subject is often stronger than that toward their employer. For them, remaining up to date with their knowledge is more important than financial aspects, and they will not insist on a working day with only seven or eight hours and free weekends. What they do possesses a central value in their lives. That is why it is important for these people to focus on their work as their central interest in life. What is motivating them are challenging projects rather than money or leisure time. They wish for autonomy to pursue their own interests and to go their own way. Such persons can be motivated very well by means of further education, training, participation in workshops and conferences—and far less by money.

In future organizations, many employees will be working only temporarily, by project, or part time. People may experience the same working conditions in very different ways. Part-time, project, or temporary work is seen by one group as lacking security or stability, and such employees will not identify themselves with an organization and will show little commitment. But there are also a lot of people for whom this status is convenient. They need a lot of personal flexibility and freedom and are often mothers, older employees, or persons who dislike restrictions by organizational structures. For this group of persons, the long-term prospect of permanent status is more important, and therefore more motivating, than momentary financial incentives. Just as motivating, probably, is the offer of continuous education and training that helps to augment one's market value.

### 4.4 Impact in "Management"

Under the perspective of a practical impact "motivation" plays a considerable role in most newer management discussions of:

- Values of entrepreneurship and sustainability
- Modern principles of leadership and corporate governance in agile enterprises
- Models and strategies for an adaptive and efficient organizational and personnel development
- Identification and realization of innovation chances and/or improvement of competitive processes, especially for hybrid products and the industrialization of services (Luczak and Gudergan, 2007, 2010)

No doubt, the "will to act" is an essential feature of modern management (Hausladen, 2007) that is grounded in human factors research in goal setting and goal realization, for example. Thus human factorsknowledge penetrates into the domain of company organization.

## 5 PRACTICAL EXPERIENCES FROM EUROPEAN STUDIES

Extreme working conditions, which could have been met in the early days of industrialization, with excessive daily hours, children's work, high risks of accidents, and the nonexistence of social security programs, are features of the past, at least in most industrialized countries. In these countries, however, a successive change in attitude with respect to working conditions took place in the early 1960s. Conditions of the working environment such as noise, toxic substances, heat, cold, high physical loads, high levels of concentration, monotonous short-cycle repetitive work, or impaired communication met decreasingly with the pretensions of working people (Kreikebaum and Herbert, 1988; Staehle, 1992). As a result, working people increasingly depreciated shortcomings in work design and answered with "work to rule" (Schmidtchen, 1984) or hidden withdrawal. In Germany, an increased number of complaints about working conditions, increasing dissatisfaction, and decreasing working morale were observed, for instance, by Noelle-Neumann and Strümpel (1984).

Since the early 1970s, the term *quality of working life* (QWL) has developed into a popular issue both in research and in practice. In its early phase it has often been defined as the degree to which employees are able to satisfy important personal needs through their work and experience with the organization. According to the ideas of organizational psychology, projects of organizational development should particularly create a working environment in which the needs of the employees are satisfied. Management saw this movement as a good possibility of increasing productivity and therefore supported it. What were needed were satisfied, dedicated, motivated, and competent employees who were connected emotionally to the organization. These early perceptions of quality of working life have been concretized in the meantime, but also diversified. Like any other movement with broadly and diffusely defined goals, this one produced programs, claims, and procedures differing in respect to content and a variety of at least overlapping terms often being used synonymously. Besides *quality of working life*, there are terms

such as *humanization of work* (Schmidt, 1982; Hettlage, 1983), *sociotechnical systems* (Cummings, 1978), *industrial democracy* (Andriessen and Coetsier, 1984; Wilpert and Sorge, 1984), *structuring of work*, and others.

The typical characteristics of a high-quality work environment can be summarized as follows: (1) adequate and fair payment; (2) a secure and healthy work environment; (3) guaranteed basic rights, including the principle of equality; (4) possibilities for advancement and promotion; (5) social integration; (6) integration of the entire lifetime or life span; (7) an environment that fosters human relations; (8) an organization with social relevance; and (9) an environment that allows employees to have a say or control of decisions concerning them.

Pursuit of these goals for the creation of a work environment with a high-quality work structure reaches back to Herzberg et al. (1959), who assigned them an extremely important role. In research on extrinsic or hygiene factors, Herzberg came to the conclusion that motivation of employees is increased not through higher payment, different leadership styles, or social relations at the workplace but only through considerable change in the type and nature of the work itself (i.e., task design). Certainly, today, there are still a lot of workplaces (e.g., in mass production and in the service sector) that do not meet these requirements, although they have been altered or even replaced to an increasing degree by means of new technologies.

In the 1970s and 1980s, in the light of the quality of working life discussion, many European countries initiated programs of considerable breadth to support research for the humanization of working life. From a motivational point of view, the focus of interest in these action research projects was on (1) avoiding demotivation caused by inadequate workplace and task designs and (2) supporting intrinsic motivation by identifying and designing factors that provide such potential. Researchers basically built on earlier empirical studies that investigated informal groups of workers. Studies were carried out in the United States, where groups in the Hawthorne plant of Western Electric were surveyed in the late 1920s (Roethlisberger and Dickson, 1939), and in Great Britain at the Durham coal mines, where the influences of technology-driven changes on autonomous groups were surveyed in the 1940s (Trist and Bamforth, 1951). In fact, these studies had a considerable influence on such concepts and movements as sociotechnical systems, industrial democracy, quality of working life, and humanization of work, which all are more or less centered around task design and motivation. In the following sections several programs and projects are outlined. This selection is meant neither as a rating of projects nor as a devaluation of programs or projects not discussed.

### 5.1 German Humanization of Working Life Approach

As early as 1922, Hellpach conducted a survey of group work experiments in a German car manufacturing company (Böhrs, 1978). Shifting task design from timed assembly lines toward small groups which were able to organize a certain scope of work autonomously, the company enhanced the content and extent of tasks and therefore fostered intrinsic motivation of the workers. In 1966, the German company Klöckner-Moeller abolished automated assembly lines and changed over to assembling their electrical products at single workplaces and within work groups. Other companies partially followed Klöckner-Moeller, including Bosch, Siemens, BMW, Daimler-Benz, Audi, and Volkswagen (Kreikebaum and Herbert, 1988). However, changes in these companies were by no means as far-reaching as those of some Norwegian or Swedish companies (see Section 5.2.2).

Organizational players in German companies can be divided into (1) representatives of the owners (management), (2) representatives of the employees (works councils), and (3) employees. A works council has to be informed by management of several issues of "information rights." The works council can enter objections to other issues of "participation possibilities," and regarding issues of "participation rights" the works council has to be asked for permission by management: for instance, when it comes to employing new persons. In the German Occupational Constitution Act (Betriebsverfassungsgesetz) of 1972, management and works councils were obligated to regard results of work science in order to design work humanely. Compared with other countries, this was novel.

In 1974, the German Federal Secretary of Research and Technology [Bundesministerium für Forschung und Technologie (BMFT)] initiated the program "Research for the Humanization of Working Life" [Humanisierung des Arbeitslebens (HdA)] and funded about 1600 studies from 1974 to 1988. In 1989, this program was followed by the strategic approach "Work and Technology" [Arbeit und Technik (AuT)], which besides humanization focused particularly on technology and rationalization aspects. In 1999, this program was succeeded by the program "Innovative Work Design—Work of the Future" [Zukunft der Arbeit (ZdA)], where (among others) humanization aspects with respect to the service sector have been of interest. So far, about 3400 single projects have been funded with the help of these three German programs. These projects were accomplished with the assistance of one or more research institutes, which carried out accompanying engineering, psychological, medical, or sociological research. They usually received between 10 and 20% of the funds cited in Figure 8. Objects of research were the survey of actual conditions as well as the implementation and evaluation of solutions with respect to workplace design, task design, or environmental influences in one or more companies or organizations out of all branches and fields that one could imagine.

Therefore, these case studies were carried out primarily with industrial partners from mechanical engineering, the mining and steel-producing industry, the electrical industry, the automotive industry, the clothing industry, the chemical industry, the food-processing industry, and the building industry. However, workplaces were also surveyed in service branches such as the hotel and catering industry, the transport industry (including trucking, harbor, and airports), the retail industry, railway transportation, postal services, merchant shipping, and
**Figure 8** Funds provided in German ''Humanization of Working Life'' (HdA) studies and the succeeding programs ''Work and Technology'' (AuT) and ''Innovative Work Design—Future of the Work'' (ZdA), in million euros.

health care. In recent years, aspects of humanization have become less important in these projects, which is very unfortunate in light of the fact that employees in the automotive industry, for example, and in the "new economy" faced increasingly inhumane working conditions.

The HdA program, including its successors, AuT and ZdA, is not the only German program that funded research on humanization and quality of working life projects. Regarding the qualification of employees, the program of the Federal Secretary of Economy [Bundesministerium für Wirtschaft (BMFW)] funded projects with 350 million euros from 1994 until 1999, with about 150 million euros being provided by the European Social Fund (ESF) (BMWA, 2003). Additionally, several other programs could be mentioned, such as those initiated by the federal states in Germany.

### 5.1.1 Goals of the HdA Program

In terms of task design and motivation, the HdA program focused initially on avoiding demotivation caused by shortcomings in fulfillment of basic needs of workers. Later, issues such as increasing motivation of workers by introducing new forms of work organization became more and more important. Basic goals as propagated by the Federal Secretary were as follows (Keil and Oster, 1976): (1) development of standards of hazard prevention, reference values, and minimum requirements regarding machines, installations, and workplaces; (2) development of humane working techniques; (3) development of exemplary recommendations and models for work organization and task design; (4) distribution and

application of scientific results and insights; and (5) supporting economy in implementing these insights practically. With respect to particular areas of work design, the focus of interest was on assessing and reducing risks of accidents; environmental influences such as noise, vibration and concussion, and hazardous substances; as well as physical and psychical stress and strain at work.

In the scope of this chapter, the following HdA goal (Keil and Oster, 1976) is of particular interest: Influences of task design should be surveyed with respect to the organization of work processes, structures of decision making and participation, planning of labor utilization, remuneration, and occupational careers as well as satisfaction and motivation. Around 1975, the focus of interest in industrial research projects shifted. Before the shift, projects with a strong focus on reducing risks of accidents or physical stress and strain of workers were funded. After an increase in funding volume in 1975, studies with a focus on introducing new organizational structures in the fields of production or administration began to play a more important role (Kreikebaum and Herbert, 1988).

### 5.1.2 Quantitative Analysis of HdA Studies

Aspects of motivation were of special interest in many of the HdA projects. Even though these aspects played an only partial starring role, they can be considered as a common ground for all studies. Unfortunately, in the beginning of the HdA program, the central funding organization, the German Aerospace Center [Deutsches Zentrum für Luft- und Raumfahrt (DLR)], neglected a systematic documentation of all funded

projects by not forcing the receiving organizations to standardize the documenting of results. Therefore, today a complete investigation of these funded projects is almost impossible.

The quantitative analysis of funded action research studies as depicted in Figures 8-10 draws on the work of Brüggmann et al. (2001), who gathered a database of about 35,000 sets of journal articles from various fields of occupational safety and health (OSH), aiming to identify tendencies in OSH particularly between research work done in different countries. Additionally, project descriptions of more than 4000 projects of HdA and AuT and of other German project-funding institutions, such as the Federal Agency of Occupational Safety and Health [Bundesanstalt für Arbeitsschutz und Arbeitsmedizin (BauA)] or the legally obligated Mutual Indemnity Association [Berufsgenossenschaft (BG)], have been gathered. Since only the HdA, AuT, and ZdA studies are of interest in this chapter, the remaining studies and the OSH literature have been ignored. For simplicity, the term "HdA studies" may be used for both AuT and ZdA studies.

In the database there were fields available such as title, accomplishing institutes, funding period, and keywords for studies. Titles of studies combined with keywords provide a high information density which can be compared to articles with available title and abstract. To be able to classify the data sets correctly, an elaborate, hierarchical system of criteria with manifold combinations of logical AND, OR, and NOT matches of thousands of buzzwords was developed by Brüggmann. The classification hierarchy was then validated empirically by several experts.

In this chapter the set of criteria has been expanded and adapted to the scope of task design and motivation. Since the number of available data sets of studies (carried out between 1974 and 2004) as well as the amount of available relevant information varied over time, a representation in relative percentages has been chosen for depicting time-based characteristics; 100% in the diagrams indicates 100% of all data sets that have at least one hit for each criterion.

The results of the quantitative analysis can be used to balance HdA studies with respect to several aspects of task design and motivation. To do so, three boundaries for the respective scope have been chosen. These boundaries, in turn, contain several criteria, which might be of special interest and therefore build up a hierarchical system. In terms of *system theory*, a criterion in one scope can again build up its own scope, such as "task design" in Figure 9. The first scope of interest covered all funded studies versus studies that are relevant for task design and motivation, as depicted in Figure 8. The second scope covered all studies that are relevant for task design and motivation, as depicted in Figure 9.

The first thing that stands out is the continually decreasing proportion of studies that cover aspects of task design, even though the hits for "leadership/ autonomy" could also be counted as "task design" (interpreting them as autonomy according to Hackman and Oldham's job characteristics model). The second remarkable characteristic is the increased proportion of

both "leadership/autonomy" and "incentives." In recent years, especially incentives have become a big issue in funded studies. But aspects of leadership increasingly gained influence. Two representative projects that address questions of leadership are "Modern Services by Innovative Processes of Organization" (MoveOn) and "Flexible Cooperation with Information and Communication Technologies" (SPICE). Breaking "task design" down into "feedback," "task significance," "task identity," or "skill variety," the proportions depicted in Figure 10 can be observed.

Again, light trends can be deduced from the characteristics pictured. The courses of "skill variety" and of "task identity" seem to follow a steady downward tendency. This could be explained by the trend of tasks becoming more and more demanding, making research in this field redundant. An aspect that has become more and more important in recent years is feedback from the task carried out. Aspects of "task significance" gained influence similarly. After all, quantitative analysis gives hints about which fields have been in researchers' and funding organizations' focuses of interest and how these have been objects of shifts over the years.

### 5.1.3  Selected Case Studies

The following is a small selection of typical HdA-funded projects. The aim of this selection is to give an idea of how diversified—in terms of surveyed types of workplaces—the scope of this program was. Furthermore, only case studies from the first years of this program have been selected, since these studies reached a certain degree of recognition within the German scientific community and all of these studies had the character of a role model with respect to succeeding HdA projects. However, many other studies within the HdA program revealed countless scientifically and practically valuable results and insights as well. For more details regarding these studies, the reader is referred to BMFT (1981).

***Electrical Components Industry: The Case of Bosch***  The original title of the Bosch 1 study was "Personalentwicklungsorientierte Arbeitsstrukturierung" ("Structuring of Work with Focus on the Development of Employees"). It was accomplished by the Institute of Work Science of the Technical University of Darmstadt (IAD), the Institute of Production Technology and Automation of the Fraunhofer-Gesellschaft in Stuttgart (IPA), the Institute of Sociology of the University of Karlsruhe (IfS), and the Working Group of Empirical Research in Education in Heidelberg (AfEB), in cooperation with the Robert Bosch GmbH, a global player in the electric and automotive industry. The project was funded from 1974 to 1980 with about 10 million euros.

The primary goal was the development of new forms of work organization in the field of assembling products of varying complexity, such as car radios, cassette decks, TV sets, speakers, electrical tools, and dishwashers. With respect to task design and motivation in many of the plants considered, the contents of work were expanded in order to realize the concept of job enrichment. Technically, this was done by decreasing the degree of automation. In the plant at Herne, tasks
**Figure 9** Proportions (five-year moving averages) of several criteria of HdA studies relevant for task design and motivation.

**Figure 10** Proportions (five-year moving averages) of several criteria of task design studies.

for the assembly of car speakers were considered. The time for a task for which an employee was responsible increased from 0.3 to 1.5 min on average. In the plant at Hildesheim, the assembly of car cassette decks was considered. Here, the increase in time was from about 1.0 to about 5.5 min. Considering a flow assembly with an average working time of up to 1 min for each worker, the time spent for one assembly could be

extended to about 1 h by combining functionally different tasks. Additionally, logistical tasks were done by the group. Other projects in the plants of Hildesheim, Leinfelden, and Dillingen were concluded with similar results. The project team established a "learning on the job" concept in these projects, which was close to the job rotation approach. Additionally, a qualification approach for implementing advanced social structures was applied

and evaluated. The scope of actions and decision making was increased by a decoupling of conveyor belts, and the cycle of tasks by means of buffers. Therefore, employees could, to a certain degree, dispose of their own work. The researchers predicted a great potential in the self-disposing of work systems. However, strong participation by employees was considered essential. In some of the groups surveyed, they even found that workers took over disposing activities without any authority.

### Automotive Industry: The Case of Volkswagen

The German title of this case study was "Untersuchung von Arbeitsstrukturen im Bereich der Aggregatefertigung der Volkswagen AG Salzgitter" ("Survey of Structures of Work in the Field of Aggregate-Assembly of Volkswagen"). It was accomplished by the Institute of Work Science of the Technical University of Darmstadt (IAD), the Institute of Work Psychology of the ETH Zurich (IfAP), and the Institute of Production Technology and Automation of the Fraunhofer-Gesellschaft in Stuttgart (IPA) in cooperation with Volkswagen AG, one of the biggest car manufacturers in the world. The project was funded from 1975 to 1978 with about 5.5 million euros.

The primary goal of this project was the analysis of conventional and new forms of work structures in the field of manufacturing aggregates in the automotive industry. Therefore, a qualitative as well as a quantitative evaluation of person-specific as well as monetary criteria was aimed at, both cross-sectioned and longitudinal-sectioned, with a time frame of three years. The objectives of the research were the concepts of (1) conventional assembly line with pallets, (2) intermittent transfer assembly, and (3) assembly groups. In all three alternatives, the variables of feasibility, tolerability, reasonability, and satisfaction were investigated. Remarkable at this point were the open-minded employees of Volkswagen: 268 of 450 potential participants volunteered to participate in the project.

The alternative of assembly groups embodied the concept of job enrichment, where tasks formerly automated were now handled additionally by the group. Even though this implied partially increased stress for the persons involved, the overall distribution of stress was perceived as being more favorable. After all, psychologists found that satisfaction of workers in assembly groups was significantly higher than in the other alternatives. Furthermore, this work was perceived as being more demanding.

Finally, Volkswagen evaluated the results and came to the following conclusions:

1. Many improvements in work and task design will be accounted for in future corporate planning.

2. Stress resulting from work in all three alternatives was on a tolerable level; only partially significant differences could be verified.

3. The proposed new form of work organization competed with established rules, agreements, and legal regulations for distribution of tasks in companies.

4. Mandatory preconditions for implementing a comprehensive process of qualification were individual skills and a methodical proceeding incorporating adequate tools and techniques.

5. Decisions regarding the introduction of new forms of work organization depended on expectations about long-term improvements resulting from that change; the evaluation of economical issues was crucial in that respect.

6. The research project made clear that, in opposition to common positions, a change in working conditions does not necessarily lead to substantial improvement. But it appeared that increased consideration of employees' desires and capabilities regarding assignment to tasks is leading to motivation of these employees.

From an economical point of view, assembly groups were considered to be cost-effective only for small lot sizes of up to 500 motors a day.

### Clothing Industry: A Case of a Total Branch

The German title of this branch project was "Neue Arbeitsstrukturen in der Bekleidungsindustrie—Branchenvorhaben" ("New Structures of Work in the Clothing Industry—Branch Projects"). It was accomplished by the Institute of Operations Research in Berlin (AWF), the Institute of Economical Research in Munich (IFO), the Country's Institute of Social Research in Dortmund, the Institute of Stress Research of the University of Heidelberg, and the Research Institute of Hochenstein, in cooperation with the German clothing union, the German Association of Clothing Industry, as well as the companies Weber, Bierbaum & Proenen, Bogner, Patzer, and Windsor. The project was funded from 1977 to 1993 with about 24.5 million euros. In fact, this was the first German project that investigated an entire branch of industry.

The primary goal of this project was the identification of possible and convertible improvements in clothing production processes. With respect to task design and motivation, changes in organizational structures and participation of employees were considered as a necessary condition to realize these improvements rather than as the actual object of research. However, it was found that shortcomings regarding task design were evident before the project started: unchallenging work; short cycle times; one-sided physical stress; piece-rate-, quality-, and time-based remuneration; low scope of disposing one's own tasks; social isolation; and demotivating leadership by directing and controlling. Only a few months after improvements in workplace and task design had been implemented (e.g., setting up groups with an enhanced scope of action), the first positive results regarding job satisfaction, communicativeness, increased qualification, and degree of performance were observed. Hence, it was possible to prove that the changes did indeed lead to increased motivation of employees. These new structures also proved to be useful in economic terms. The involved companies soon began to implement these structures in other fields as well.

### Services in Public Administration: The Case of the Legal Authority of the City of Hamburg

The German title of this project was "Verbesserung der Arbeitbedingungen bei gleichzeitiger Steigerung der Effizienz des Gerichts durch Einführung von Gruppenarbeit in den Geschäftstellen" ("Improvement of Working Conditions and Increase of Efficiency of the Legal Authority by Introduction of Group Work in Offices"). It was accomplished by the Consortium for Organizational Development in Hamburg and the Research Group for Legal-Sociology in Hannover in cooperation with the Legal Authority of the City of Hamburg. The project was funded from 1977 to 1981 with about 0.8 million euros.

The primary goals of the project were improving working conditions, improving employee job satisfaction, guaranteeing efficient operation, and decreasing the duration of processes. Therefore, group offices were implemented which could react more flexibly in the case of a varying workload. Additionally, a cutback of hierarchical structures combined with improved participation and qualification of employees should be reached. Together with a better design of communication structures and flows of information, improved service should be reached. Therefore, the researchers established four model groups: two in the field of civil law and two in the field of criminal law. The results implied that introduction of group work in large courts would be an adequate way of encountering dysfunctions by means of division of labor. Regarding the introduction of novel office technology, the results implied that an appropriate accompaniment by organizational changes can be seen as necessary. Otherwise, partial overload of employees would be possible.

### Metal Work Industry: The Case of Peiner AG

In terms of employee participation, the *Peiner model* attracted considerable attention within the German scientific community. Therefore, this project is presented here in more depth. The German Research Institute of the Friedrich-Ebert-Stiftung accomplished this action research study from 1975 to 1979 in cooperation with Peiner AG, an incorporated company in the metal work industry with about 2000 employees at that time. In the period of 1973–1974, one year before the project started, Peiner AG closed its balance sheet with 10 million euros of losses. Up to 1977–1978, these losses were reduced by 80%. The following description of the project is based on the final report of the Research Institute of the Friedrich-Ebert-Stiftung (Fricke et al., 1981).

At the beginning of the study, machinery and installation at plant I, which was mainly producing screws, were in bad shape. Production in plant I was characterized by small lot sizes and short delivery times. Due to an unsteady supply of incoming orders, utilization of both workers and machines was changing with some degree of uncertainty. Therefore, employees had an average employment guarantee of only a few days. Furthermore, wages were coupled with particular activities in the production process. Since workers had to be extremely flexible concerning the tasks they had to perform in one day (which was not meant as sanitizing

work in the sense of job rotation but was born from the necessity of the production situation), wages could differ from day to day. Altogether the situation represented considerable uncertainty for the workers. The focus of interest of the team of researchers from the Friedrich-Ebert-Stiftung was division ZII of plant I. In terms of the production flow, chipping, which was carried out in ZII, succeeded the warm-forming and cold-forming divisions. At the start of the project, 47 employees worked at ZII, where high rates of fluctuation to other divisions were observed.

With respect to workplace design, tremendous shortcomings could be found: Due to the nonergonomical shapes of machines, machine workplaces did not leave workers a choice of whether they prefer to work standing or sitting. The working heights of machine workplaces were not personally adjustable. For small persons it was not even possible to place a small platform in front of the machines. Reaching spaces for machines in ZII were designed without any consideration of percentiles of human arms. Therefore, while working in a standing position, joints, muscles, ligaments, and the vertebral column could easily be overstrained. Some control pedals on a special machine forced workers to stay solely on one foot during an entire shift of eight hours. Each raw part had to be placed into the machines manually. Especially with heavy parts, this was painful for workers. Due to boxes, bins, hand gears, actuators, raw parts, parts of machines, or tools around the machine and behind the workers, freedom of movement was cut down dramatically. These types of enforced bearing caused tremendous impairments of the human body. To actuate machines, workers had to expend enormous force. Changing from machine to machine made these workers suffer from adjustment pain, which could last a few days. Furthermore, these workers often suffered from inflammation of the synovial sheath of tendon. To keep track for piece-rate purposes, frequent clearance of chipping boxes was neglected until the boxes were overly full. Emptying 35-kg heavy boxes at a height of 1.50 m often led to overstraining by female workers and sometimes by male workers, too. To refill the cutting oil emulsion in machines, workers had to tow heavy buckets of this fluid. Various other findings indicated tremendous shortcomings in terms of today's standards of occupational safety and health.

With respect to task design, several factors that promoted physical and psychical overstrain could be observed at ZII in 1975. In addition to socially unfavorable conditions, this led to systematic demotivation and therefore to considerable withdrawal of workers at ZII, manifesting in a high rate of fluctuation. The situation in 1975 could be characterized by a high degree of division of work. A foreman was responsible for assigning jobs to machines or workers. He received all necessary papers a few weeks before the start of production from the division of job preparation. However, nobody could tell when the jobs would arrive at ZII. Usually, if the job arrived in the preliminary division, the respective craftsman sent a status message. If jobs were urgent, deadlines were short, or utilization of ZII was low, the craftsman headed in person for the next job. Division of

labor was then realized by providing several services, which were carried out by setters, mechanics, weighing machine workers, pallet jack drivers, inspectors, and shop floor typists.

Machinery workers did not have fixed workplaces and therefore changed on the basis of demand between different machines. Maintenance work on machines was carried out only if it was really necessary. The pallet jack drivers got direct orders from the foremen as to where to provide which raw materials and where to put which final materials. The setters got direct orders from the foremen as to which tools to prepare and in which machines tools had to be changed. Machinery workers got to know on which machines to work next only during the actual shift. Beginning work on a particular machine, the piece-rate ticket had to be stamped. The actual work consisted of depositing up to five parts in parallel into the machines in which they were processed. Each of these processes had to be controlled particularly. If processing of a particular piece was finished, the carriages had to be reset in the starting position by the worker. Work cycles were up to 1.8 s per piece. If the target was 100 pieces within 5 min, the performance rate was about 140%. Short cycles carried out over an entire shift of 8 h caused tremendous stress, resulting from monotony. Additionally, the workers had to spent a certain degree of attention to avoid injury to their hands, to control the quality of processed parts and to track the even operation of the machines, to refill cooling emulsion if necessary, and to request a setter if tools were about to lose sharpness. Even though workers spent this degree of attention, they soon lapsed into an automated working mode where they basically reacted habitually. Another source of demotivation arose out of the enforced cooperation between machinery workers and setters. Since machinery workers' wages depended on piece rates, the workers usually reacted angrily if the setters did not appear instantly or did not work quickly enough (from their point of view). Setters, in turn, felt provoked by machinery workers.

This unchallenging work, short cycle times, permanent attention in combination with piece-rate based remuneration, authoritarian leadership, and the other environmental conditions mentioned constituted an enormous source of stress for these employees. In consequence, this led to a cliff-hanging atmosphere, with separation of single workers, as well as competition and conflicts between co-workers.

In carrying out the project, researchers aimed basically at the following goals: First, the source of imagination would come from committed employees' ideas about how to improve work and task design, which Fricke (1975) called *qualification to innovate*. One of the goals was determining the social conditions and requirements that are necessary to mediate, apply, and unfold qualifications to innovate. At the same time, these processes of mediating and applying should indicate how these qualifications to innovate could look and what impact they could have. This goal was based on empirical findings that employees may, in fact, have qualifications enabling them to formulate innovative changes, yet they were hindered by a variety

of environmental factors, including firmly established organizational structures or resistance from colleagues or superiors. Since from a scientific point of view qualification to innovate is a potential for action, it would have to be observed to enable drawing conclusions about influencing variables. In a normal work environment, however, this observation would not have been possible, for the reasons mentioned above. Therefore, the project was planned as an action research project in which participants were enabled and encouraged to formulate and express such potential.

Furthermore, the researchers aimed at developing and testing approaches for organizing systematic processes of employees' participation in changing work design and task design. This procedure was meant to provide a frame of action for any employee to contribute to the design of working conditions. Therefore, again an action research approach had to be chosen. Finally, together with workers at ZII, actual improvements in workplace and task design were developed, which could be implemented upon approval by management. Hence, the three goals could be pursued in an integrative, simultaneous fashion.

The project could be sectioned into seven phases. The core of the project's phases were workshop weeks, where employees discussed solutions together with researchers. Additionally, project groups were built consisting of employees, ombudsmen, members of the works council, and experts. Actual solutions and suggestions for improvements were proposed to the plant's management and, when approved, were implemented. In each of these phases, countless discussions and meetings took place with superiors and management as well as with the works council. Additionally, several economic, ergonomic, and medical surveys were conducted.

The systematic procedure for employees' participation made clear that even unskilled workers are both willing and capable of participating in the design of workplaces and tasks, and therefore employees do have qualifications to innovate. With respect to the second goal, the following results could be presented. The systematic procedure of employees' participation turned out to be one possible way toward decentralization of decision-making structures, not only in industrial organizations. The research revealed preventable problems occurring when employees are not involved in workplace and task design processes. Participatory workplace and task design can lead to an increase in productivity. Fricke et al. (1981) note that such gains in productivity must not be misused. Therefore, agreements regarding distribution of resulting time in the form of rest periods, reduction in working time, and looking ahead to technical–organizational changes have to be met. From their point of view, these new approaches could be useful completions to existing legal forms of organizational participation. With respect to the third goal, the results of the six workshops should be mentioned. Altogether, 150 pages of suggestions by employees at ZII are evidence of the innovative potential and motivation of these workers.

A major result of this project was an official agreement between Peiner AG and employees: "Participation

of Employees in Designing Work Places, Tasks and Environment" in 1979 (Fricke et al., 1981). The results of the project with respect to task design and motivation of employees at ZII were not overwhelming but could be seen as a starting point for further research projects. Employees confirmed that, in addition to improvements in physical working conditions, they gained considerably in self-confidence, everyone felt "free," everyone was more capable of discussing needs and ideas, and everybody talked increasingly about working conditions and task design. Employees learned how to express their needs and who to contact in certain situations. Employee motivation to innovate in their direct work environment and task design increased significantly.

## 5.2 European Approaches to Humanization of Work

### 5.2.1 Employee Participation in Europe

Especially during the Industrial Revolution, voices that criticized inhumane working conditions in industry gained increasing influence, leading to the development of unions and labor parties. In many European countries this political influence resulted over time in legal regulations that at least assured a minimum of human rights and human dignity for industrial employees.

Scandinavian countries particularly, but also France and the Netherlands, legally codified these rights, including several forms of employee participation, in specific labor acts. With the renewed European Union guideline RL 89/391, a sort of constitution for occupational safety and health was enacted in 1989, which for the first time contained the concept of employee participation (Kohte, 1999). In this guideline as well as in country-specific legislations, participation is always implemented in the form of democratic institutions within companies.

Regarding distribution of power, two types of participation can be distinguished: (1) unilateral participation, where rules of communication and decision making are implemented either by management or by employee representatives (usually, by unionlike institutions), or (2) multilateral participation, where rules of communication and decision making may have been negotiated between management and employee representatives (Kißler, 1992). In neither of these approaches do actual workers have much influence on, or are in charge of, their actual work environment, including task design.

In opposition to legally implemented forms of participation, a management-driven form of participation, called *quality cycles* or *quality circles* (Kahan and Goodstadt, 1999), has become widespread in recent years. In these quality circles, employees gather on a regular basis to discuss actual work-related problems such as work organization, task design, or qualification matters. In many cases these cycles are well accepted by employees since they are considered as opportunities for advancement. However, programs and institutions that are implemented parallel to the actual work processes are likely not to benefit sufficiently from the inherent potential and intrinsic motivation of employees (Kißler, 1992; Sprenger, 2002). However, organizing work within autonomous groups can be seen as one

possible way to overcome these shortcomings, although both really humanize work in terms of needs and dignity as well as meeting economic demands.

### 5.2.2 European QWL Programs

In 1975, the European Foundation for the Improvement of Living and Working Conditions was established by the European Union. This organization comprises members of a respective country's governments, economies, and unions. In the years 1993–1998, this foundation carried out "Employee Direct Participation in Organisational Change" (EPOC), a major program of research dealing with the nature and extent of direct participation and new forms of work organization (Sisson, 2000). Major results were (1) the insight that a significant number of managers consider new forms of work organization as beneficial for reaching conventional business performance goals, such as output, quality, and reduction in throughput time, as well as reducing sickness and absenteeism; (2) that companies adapting new forms of work organization will probably stabilize themselves in long-term perspective, and therefore employment may increase in these companies; and (3) that there are surprisingly only a handful of organizations that actually practice integrated approaches. Uncountable programs and projects aiming at the improvement of QWL have been carried out in most European countries in recent decades.

***Norway*** In the 1960s, Norway's social partners, under the guidance of the psychologist Einar Thorsrud, initiated the "Norwegian Industrial Democracy Project" (NIDP) (Gustavsen, 1983; Kreikebaum and Herbert, 1988; Elden, 2002). Researchers around Thorsrud further developed basic ideas that had originated at the Tavistock Institute in London in the 1950s and invented new conceptual tools (Elden, 2002). The dominating form of research was the action research approach (Gustavsen, 1983). In the focus of interest was the survey of new forms of work organization. In fact, Thorsrud and his colleagues introduced the concept of autonomous groups in several industrial companies, such as Christiana Spigerverk, Hunsfos, and Norsk Hydro (Kreikebaum and Herbert, 1988). In the course of a project with Norsk Hydro, groups were in charge of an entire process beginning with the actual production up to shipping of the product. Since the new tasks were less physically straining but technically more demanding, an enhancement in employee qualifications became necessary.

The common feature in the Norwegian projects was the systematic empowerment of employees to design their own work environment. Some necessary conditions of empowerment are depicted in Table 1.

In 1977, as a "spin-off product" of the effort of all groups and organizations involved, the government enacted the Norwegian Worker Protection and Work Environment Act. This law contained regulations regarding participation of employees. In contrast to conventional legislation, participation in designing their own work environment was mentioned explicitly. In the following years, several agreements between players in the Norwegian economy and endorsements in legislation were aimed at improving QWL further in Norway.

**Table 1  Some Necessary Conditions for Empowering Participation**

| Norwegian Model | Other Models | Significant Common Features |
|---|---|---|
| Institutional and political support at ''higher'' levels | Some parity of power prior to participation | A rejection of conventional organizational design and sociotechnical systems as a source of empowerment |
| High levels of cooperation and conflict | Systematic development of bases of power | Recognition that participation can be either cooperative or empowering |
| A vision of how work should be organized | Overcoming resistance to empowerment by the powerless | Recognition of significant differences between organizational and political democracy |
| ''Do-it-yourself'' participative research | | Empowerment as learning legitimates new realities and possibilities for action from the bottom up |
| Researchers act as ''colearners,'' not as experts in charge of change | | |

*Source*: Based on Elden (2002).

**Sweden**   From the late 1960s to the present, Sweden has made considerable efforts to improve conditions of work, therefore humanizing work environments and contents. However, these reforms were in fact born in a debate between ideological voices that focused on humanization aspects and practical voices that focused on rationalization aspects in order to countervail increasing employment of foreign workers. In the 1970s, several legislative acts regarding humanization of work were enacted: Act on Employee Representation on Boards, Security of Employment Act, Promotion of Employment Act, Act on the Status of Shop Stewards, Worker Protection or Safety Act, Act on Employee Participation in Decision Making, and Work Environment Act (Albrecht and Deutsch, 2002).

The majority of Swedish research programs draw on the Swedish Fund of Work Environment [Arbetsmiljöfonden, (AMFO)]. The AMFO is a state authority that is financed by the Swedish employers. Regarding task design and motivation, two large projects can be mentioned that gained considerable recognition within the international scientific community. The first is the case of Saab-Scania, where in the late 1960s and early 1970s, 130 production groups and 60 development groups were established. As a result of these steps in the plant at Södertälje, the rate of fluctuation decreased from 100% in 1968–1969 to 20% in 1972 (Kreikebaum and Herbert, 1988). Furthermore, in the case of motor assembly, the work cycles were decoupled from automated assembly lines. The company soon began to introduce these new forms of work organization in other plants as well.

The second project we mention is the case of Volvo. No other company in the world was as radical at that time in terms of abolishing automated assembly lines. Research experiments focusing on aspects of autonomous groups were conducted in seven plants, of which the plant of Torslanda was the largest. Uncountable experiments with the 8500 employees at Torslanda provided valuable insights into how best to introduce such groups. The new plants at Skövde and Kalmar were later built with the knowledge gathered in Torslanda.

In recent years, AMFO has carried out several succeeding programs for improving QWL. One of these programs was the program for "Leadership, Organization and Participation" (LOM), which from 1985 to 1991 accomplished 72 change projects in 148 public and private organizations. The program was funded with 5 million euros (Gustavsen, 1990; Naschold, 1992). In the period 1990–1995, the "Working Life Fund" [Arbetslivsfonden (ALF)] funded 24,000 workplace programs with about 1500 million euros (Hofmaier and Riegler, 1995). To recognize the weight of this program, one should note that Sweden's overall population was only about 8 million people at that time. The Swedish government established this fund last (but not least) in fear of an overheating economy. Therefore, several regenerating funds were established by AMFO in which employers had to spend up to 10% of their profits. Out of these funds they were able to finance, for example, development programs for their employees for a period of five years.

Actually, a national program for "Sustainable Work Systems and Health" is being carried out by the Swedish Agency of Innovative Systems (VINNOVA) from 1999 to 2006. The main goals of this program regarding QWL are keeping sustainability of organizational structures as well as integrating job design with organizational design. The program is accomplished as an action research approach as well as an action learning approach. The program will be funded with about 23 million euros (Brödner and Latniak, 2002).

**France**   Traditionally, employees' participation in France was based on interaction between the two organizational players: (1) committees of employees (delegués du personnel) and (2) representatives of the employer (comité d'entreprise). The role of the delegués du personnel was to formulate complaints of employees about working conditions, mainly regarding issues of occupational safety and health (Kißler, 1988). In 1982, the

French Secretary of Labour enacted "Auroux's Act" (Lois Auroux). With that a third player gained influence: the employee itself. Based on co-determination-groups (groupes d'expression) employees got the right to directly influence their own working conditions.

In 1973, the French government founded the National Agency for Improvement of Work Conditions [Agence Nationale pour l'Amélioration des Conditions de Travail (ANACT)], which consists of representatives of the government, the economy, and the unions. ANACT, often in association with other French organizations, such as the Improvement of Work Condition Fund [Le Fonds pour l'Amélioration des Conditions de Travail (FACT)], funded several research activities with a focus on occupational health and safety and issues of QWL. Additionally, ANACT provides offices all over France where companies can be consulted in questions of workplace design, work organization, and so on.

In 1983, the French Ministry of Research launched the "Mobilize Technology, Employment, Work Program" [Mobilisateur Technology, Emploi, Travail (TET)] (Tanguy, 1986). This program aimed at establishing research potential and an academic community for investigating, among others, forms of work organization. In 1989, the "Mobilize Man, Work and Technology" [Homme, Travail et Technologie (HTT)] program succeeded. The aim of this program was to investigate all dimensions of work, such as physical, physiological, psychological, social, and organizational. The second goal of this program was to conduct increasing action research.

In 1984, the National Center for Scientific Research [Centre National de la Recherche Scientifique (CNRS)] launched the "Interdisciplinary Research Program on Technology, Work, and Lifestyles" [Programme Interdisciplinaire de Recherche sur les Technologies, le Travail et les Modes de Vie (PIRTTEM)]. This program focused mainly on projects on the development of technology and respective influences on work organization, especially on employees accepting or not accepting new technologies.

From 1983 to 1985, for example, a consortium of ANACT, TET, and the "Action for Improving Work Conditions in the Alsace" [Action pour l'Amérilation des Conditions de Travail en Alsace (ACTAL)], as well as the CNRS research group of Group Lyonnais de Sociologie Industrielle (GLYSI) and a management consultant, accomplished an action research project in the Moulhouse plant of the car manufacturer Peugeot. The project was called "Social and Organizational Impact of Automation and Robotics" [Impact Social et Organisationnel des Automatismes et de la Robotique (ISOAR)] (Coffineau and Sarraz, 1992). The project basically aimed at preparing the company for future investment in automation technology. New organizational and social equilibriums resulting from that change were to be identified. Employees in the affected parts of the plant were to be developed and qualified accordingly. Therefore, a new concept of participation consisting of three hierarchical levels was established. The first level dealt with shop floor working groups comprising superiors, foremen, workers, and union members. The second level consisted of superiors, a production engineering group, union members, and public representatives. Finally, the third level consisted of representatives from management, the unions, and public organizations.

***Great Britain***   In the advent of European humanization approaches, Great Britain's companies could not provide legally codified forms of employee participation (i.e., there were neither any works councils nor any forms of written agreements on the management level) (Heller et al., 1980). However, some of the roots of humanization of working life can be found in Great Britain: namely, in research at the Tavistock Institute of Human Relations in London, where the concepts of sociotechnical systems and the quality of working life (QWL) emerged. Most notably, the Tavistock coal-mining study of Trist and Bamforth (1951) contributed to the insight that technical innovations in the workplace and task design cannot be applied without regard to the social impact these changes can have on employees. Trist discovered that workers in the Durham coal mines who for decades had worked in autonomous groups barely accepted new, technology-driven forms of work which forced them to abandon the social relations that had grown up among the old group. Furthermore, the impact of concepts such as content of work, extent of work, order of tasks, and degrees of control and feedback on the work's output and on the motivation of workers was investigated. The results can be seen as the foundations of well-known concepts: job enrichment, job enlargement, job rotation, and work organization in autonomous groups.

Even though we could mention other projects that investigated humanization and participation aspects in Great Britain (e.g., several British car manufacturers, the aerospace industry, Indian textile mills), no governmental programs comparable to HdA, AuT, AMFO, or ANACT were accomplished at that time. In 1999, the British Prime Minister carried out The "Partnership at Work Fund," which until 2004 has funded projects with about 14 million pounds sterling. The program focuses on improving relations among organizational players where issues of employee participation are of particular interest (Brödner and Latniak 2002).

## 5.3   Summary of European Studies

Changing actual working conditions as well as scientific insights and implications for work design naturally resulted in conflicts among the involved organizational and societal players. Employer federations argued that humanization must not lead to a shift in responsibilities and power. Beyond that, however, voices from this side admitted that humanization goals do not necessarily compete with economical goals. Employee federations criticized many of the studies as leading to an implementation of measures of rationalization, with the consequence of increased unemployment. Apart from that, employee federations such as unions or works committees widely supported the humanization efforts.

Although these humanization studies have been carried out considering different forms of work and workplaces in different types of companies and branches,

one common aspect can be identified in all the projects: task design and motivation. Whether surveying the Durham coal mines, the assembly lines of Bosch, Saab, Volvo, or Volkswagen, the clothing industry, or authorities of cities and countries in retrospect, if one talks about enlarging work contents and extents, the scope of responsibilities, the possibilities for organizing work in groups, and employee qualifications, one also talks about factors that may influence the intrinsic motivation of employees. Speaking with Maslow: social or esteem needs; speaking with Alderfer: growth needs; speaking with Herzberg: satisfiers and dissatisfiers—these were all addressed substantially in these studies. Herzberg's two-factor theory and Hackman and Oldham's job characteristics model can be seen especially as a basic source of inspiration for most of the practical task design solutions that have been surveyed in the action research studies mentioned.

But also in those studies that surveyed primarily the influences of work environment on employee safety and health (which have not been taken into account in Figure 8), issues of motivation actually provide the common ground. That is, whether these studies focused on development of standards of hazard prevention or on reducing physical stress and strain for workers, these issues can be connected to fulfillment of basic needs of employees according to the content theories of motivation.

Recapitulating, one could argue that from an employer's point of view the humanization of work (as well as the quality of working life, work life balance, etc.) debates led to a better understanding of the needs and motives of employees. Facing the tremendous change in attitude with respect to working conditions that occurred in the 1960s, these insights provided room for reducing demotivation of employees substantially, therefore improving productivity and quality of work results. However, there are voices (Sprenger, 2002) that postulate a new shift of employee attitudes with respect to motivational techniques and incentive systems. They give warning of focusing on manipulating employees' extrinsic motivation. In their opinion, such forms of leadership can easily lead to incentive-dependent employees in the best case—or to demotivated employees who feel that they are being treated as immature and are not taken seriously in the worst case. From an employee's point of view, these debates and the resulting changes can be assessed as a noteworthy contribution to improvement in the quality of working life. For single employees, however, these new forms of work organization often come together with increased stress and strain, which can be partially balanced by increased efforts at qualification.

Considering all the new challenges that the information age has evoked for working conditions, one can recognize that there is still a lot of research to be conducted. The development of new forms of work organization leading to increasingly demanding, highly complex tasks has generated a new source of stress for employees which cannot simply be countervailed by measures of qualification. Along with inhumane pressure of time and a competitive culture, this results

more and more in psychosocial diseases such as the well-known burnout syndrome. Furthermore, there is little knowledge of the long-term effects of manipulative motivational techniques on employee motivation and achievement potential. From a practical point of view, commonsense task design that accounts for both motives and the dignity of human beings appears to be one of the keys in facing these challenges.

## 5.4 Recent Developments

Beginning in the 1990s and reinforced by employment problems in 2000++ the focus of most governmental programs for the improvement of working conditions changed from a physical product and production type view in terms of technology to the until-then underrated and underrepresented "services" (Luczak, 1999; Luczak et al., 2004). Nowadays this development has reached the international scientific community and multiple practitioners' groups under the heading "service engineering" (Salvendy and Karwowski, 2010) as a new branch of a comprehensive service science approach. No doubt that human factors thoughts in service product development processes, service production organizations, and teaching approaches for the new discipline of service engineering play a dominant role in this context: "Task and motivation"–related knowledge forms a kernel of ideas and competencies transferable from physical goods' production to service production (Luczak and Gudergan, 2010).

Besides a shift to the task type "service" the "humanization" approaches in public programs were oriented to "good work" too. The term was invented and propagated by the unions to counteract the employers' tendency to precarious forms of work and to find new ways to compensate the tendency to a shrinking membership. In fact the discussion centers around criteria and their combination (Fuchs, 2009; Prümper and Richenhagen, 2009; Landau, 2010) that have a lot to do with "task design and motivation": Good work is:

- Senseful and satisfactory (work satisfaction)
- Qualifying with open ways to career and development possibilities
- Stable and regular in employment
- Well paid (just and reasonable) and balanced in terms of a work to family life account
- Sane, not only safe
- Limited in resource consumption, especially emotional stressors, by leadership and company culture
- Balanced in work intensity and working hours
- Communicative to colleagues, having free information flows, and influential in terms of self-set design possibilities
- And so on

On the whole, the basic idea is that work/tasks can be perceived by the working person as being a fountain of well-being and of personality development and an improvement of self-esteem.

## 1 INTRODUCTION

### 1.1 Job Design

Job design is an aspect of managing organizations that is so commonplace it often goes unnoticed. Most people realize the importance of job design when an organization or new plant is starting up, and some recognize the importance of job design when organizations are restructuring or changing processes. But fewer people realize that job design may be affected as organizations change markets or strategies, managers use their discretion in the assignment of tasks on a daily basis, people in the jobs or their managers change, the workforce or labor markets change, or there are performance, safety, or satisfaction problems. Fewer yet realize that job design change can be used as an intervention to enhance organizational goals (Campion and Medsker, 1992).

It is clear that many different aspects of an organization influence job design, especially an organization's structure, technology, processes, and environment. These influences are beyond the scope of this chapter, but they are dealt with in other references (e.g., Davis, 1982; Davis and Wacker, 1982). These influences impose constraints on how jobs are designed and will play a major role in any practical application. However, it is the assumption of this chapter that considerable discretion exists in the design of jobs in most situations, and the job (defined as a set of tasks performed by a worker)

is a convenient unit of analysis in both developing new organizations or changing existing ones (Campion and Medsker, 1992).

The importance of job design lies in its strong influence on a broad range of important efficiency and human resource outcomes. Job design has predictable consequences for outcomes including the following (Campion and Medsker, 1992):

1. Productivity
2. Quality
3. Job satisfaction
4. Training times
5. Intrinsic work motivation
6. Staffing
7. Error rates
8. Accident rates
9. Mental fatigue
10. Physical fatigue
11. Stress
12. Mental ability requirements
13. Physical ability requirements
14. Job involvement
15. Absenteeism
16. Medical incidents
17. Turnover
18. Compensation rates

According to Louis Davis, one of the most prolific writers on job design in the engineering literature over the last 35 years, many of the personnel and productivity problems in industry may be the direct result of the design of jobs (Davis, 1957; Davis et al., 1955; Davis and Taylor, 1979; Davis and Valfer, 1965; Davis and Wacker, 1982, 1987). Unfortunately, people mistakenly view the design of jobs as technologically determined and inalterable. However, job designs are actually social inventions. They reflect the values of the era in which they were constructed. These values include the economic goal of minimizing immediate costs (Davis et al., 1955; Taylor, 1979) and theories of human motivation (Steers and Mowday, 1977; Warr and Wall, 1975). These values, and the designs they influence, are not immutable givens but are subject to modification (Campion and Medsker, 1992; Campion and Thayer, 1985).

The question then becomes: What is the best way to design a job? In fact, there is no single best way. There are several major approaches to job design, each derived from a different discipline and reflecting different theoretical orientations and values. This chapter describes these approaches, their costs and benefits, and tools and procedures for developing and assessing jobs in all types of organizations. It highlights trade-offs which must be made when choosing among different approaches to job design. This chapter also compares the design of jobs for individuals working independently to the design of work for teams, which is an alternative to designing jobs at the level of individual workers. This chapter presents the advantages and disadvantages of designing work around individuals compared to designing work for teams and provides advice on implementing and evaluating the different work design approaches.

## 1.2  Team Design

The major approaches to job design typically focus on designing jobs for individual workers. However, the approach to work design at the level of the group or team, rather than at the level of individual workers, is gaining substantially in popularity, and many U.S. organizations are experimenting with teams (Guzzo and Shea, 1992; Hoerr, 1989). New manufacturing systems (e.g., flexible, cellular) and advancements in our understanding of team processes not only allow designers to consider the use of work teams but often seem to encourage the use of team approaches (Gallagher and Knight, 1986; Majchrzak, 1988).

In designing jobs for teams, one assigns a task or set of tasks to a team of workers, rather than to an individual, and considers the team to be the primary unit of performance. Objectives and rewards focus on team, not individual, behavior. Depending on the nature of its tasks, a team's workers may be performing the same tasks simultaneously or they may break tasks into subtasks to be performed by individuals within the team. Subtasks can be assigned on the basis of expertise or interest, or team members might rotate from one subtask to another to provide variety and increase breadth of skills and flexibility in the workforce (Campion and Medsker, 1992; Campion et al., 1994b).

Some tasks are of a size or complexity or otherwise seem to naturally fit into a team job design, whereas others may seem to be appropriate only at the individual job level. In many cases, though, there may be a considerable degree of choice regarding whether one organizes work around teams or individuals. In such situations, the designer should consider advantages and disadvantages of the use of the job and team design approaches with respect to an organization's goals, policies, technologies, and constraints (Campion et al., 1993).

## 2  JOB DESIGN APPROACHES

This chapter adopts an interdisciplinary perspective on job design. Interdisciplinary research on job design has shown that different approaches to job design exist. Each is oriented toward a particular subset of outcomes, each has disadvantages as well as advantages, and trade-offs among approaches are required in most job design situations (Campion, 1988, 1989; Campion and Berger, 1990; Campion and McClelland, 1991, 1993; Campion and Thayer, 1985; Edwards et al., 1999, 2000; Morgeson and Campion, 2002, 2003).

While not new, contemporary work design researchers and practitioners have begun to reintegrate social and contextual aspects of employees' work with the characteristics traditionally studied by job design. These approaches to work design have since led to new approaches and have become incorporated into new assessment tools (Morgeson and Humphrey, 2006; Morgeson et al., 2010; Humphrey et al., 2007; Grant and

Parker, 2009). Building off and integrating the suggestions made in Campion's (1988; Campion and Thayer, 1985) interdisciplinary model of job design (MJDQ), the work design questionnaire (WDQ) represents a new tool with which to assess work design (Morgeson and Humphrey, 2006). This measure broadens the scope, discussion, and measurement of job design through the use of three broad categories of work characteristics (motivational, social, and work context). The WDQ assesses the job and its link to the worker's social and physical context and allows job designers to assess important yet infrequently studied aspects of work design such as knowledge/ability characteristics and social characteristics. A key difference between the MJDQ and WDQ is the perspective from which the job design is assessed. In the original MJDQ each perspective (mechanistic, motivational, perceptual–motor, and biological) is proposed to assess a different set of design principles intended to create different outcomes and thus appeal to a different set of stakeholders (Campion and Thayer, 1985). On the other hand, the WDQ aims to include the concerns of each approach captured in the MJDQ (with more emphasis on the motivational, perceptual–motor, and biological approaches than the mechanistic approach), along with social and contextual concerns in a single approach to designing better work. Based on a framework developed by Morgeson and Campion (2003), the authors used three categories to integrate aspects of work design (motivational, social, and contextual). The four major approaches to job design are reviewed below with a discussion of the applicability of the WDQ characteristics included. Table 1 summarizes the job design approaches and Tables 2 and 3 provide specific recommendations according to the MJDQ (Table 2) and the WDQ (Table 3). The team design approach is reviewed in Section 3.

## 2.1 Mechanistic Job Design Approach

### 2.1.1 Historical Development

The historical roots of job design can be traced back to the idea of the division of labor, which was very important to early thinking on the economies of manufacturing (Babbage, 1835; Smith, 1776). Division of labor led to job designs characterized by specialization and simplification. Jobs designed in this fashion had many advantages, including reduced learning time, saved time from not having to change tasks or tools, increased proficiency from repeating tasks, and development of specialized tools and equipment.

A very influential person for this perspective was Frederick Taylor (Hammond, 1971; Taylor, 1911). He explicated the principles of scientific management, which encouraged the study of jobs to determine the "one best way" to perform each task. Movements of skilled workmen were studied using a stopwatch and simple analysis. The best and quickest methods and tools were selected, and all workers were trained to perform the job the same way. Standard performance levels were set, and incentive pay was tied to the standards. Gilbreth (1911) also contributed to this design approach. With time-and-motion study, he tried to eliminate wasted

movements by the appropriate design of equipment and placement of tools and materials.

Surveys of industrial job designers indicate that this "mechanistic" approach to job design has been the prevailing practice throughout this century (Davis et al., 1955; Taylor, 1979). These characteristics are also the primary focus of many modern-day writers on job design (e.g., Mundel, 1985; Niebel, 1988) and are present in such newer techniques as lean production (Parker, 2003). The discipline base for this approach is early or "classic" industrial engineering.

### 2.1.2 Design Recommendations

Table 2 provides a brief list of statements that describe the essential recommendations of the mechanistic approach. In essence, jobs should be studied to determine the most efficient work methods and techniques. The total work in an area (e.g., department) should be broken down into highly specialized jobs assigned to different employees. The tasks should be simplified so skill requirements are minimized. There should also be repetition in order to gain improvement from practice. Idle time should be minimized. Finally, activities should be automated or assisted by automation to the extent possible and economically feasible.

### 2.1.3 Advantages and Disadvantages

The goal of this approach is to maximize efficiency, in terms of both productivity and utilization of human resources. Table 1 summarizes some human resource advantages and disadvantages that have been observed in research. Jobs designed according to the mechanistic approach are easier and less expensive to staff. Training times are reduced. Compensation requirements may be less because skill and responsibility are reduced. And because mental demands are less, errors may be less common. Disadvantages include the fact that extreme use of the mechanistic approach may result in jobs so simple and routine that employees experience low job satisfaction and motivation. Overly mechanistic, repetitive work can lead to health problems such as repetitive-motion disorders.

## 2.2 Motivational Job Design Approach

### 2.2.1 Historical Development

Encouraged by the human relations movement of the 1930s (Hoppock, 1935; Mayo, 1933), people began to point out the negative effects of the overuse of mechanistic design on worker attitudes and health (Argyris, 1964; Blauner, 1964). Overly specialized, simplified jobs were found to lead to dissatisfaction (Caplan et al., 1975) and adverse physiological consequences for workers (Johansson et al., 1978; Weber et al., 1980). Jobs on assembly lines and other machine-paced work were especially troublesome in this regard (Salvendy and Smith, 1981; Walker and Guest, 1952). These trends led to an increasing awareness of employees' psychological needs.

The first efforts to enhance the meaningfulness of jobs involved the opposite of specialization. It was recommended that tasks be added to jobs, either at the

*Note:* Advantages and disadvantages based on findings in previous interdisciplinary research (Campion, 1988, 1989; Campion and Berger, 1990; Campion and McClelland, 1991, 1993; Campion and Thayer, 1985). Table adapted from Campion and Medsker (1992).

same level of responsibility (i.e., job enlargement) or at a higher level (i.e., job enrichment) (Ford, 1969; Herzberg, 1966). This trend expanded into a pursuit of identifying and validating characteristics of jobs that make them motivating and satisfying (Griffin, 1982; Hackman and Oldham, 1980; Turner and Lawrence, 1965). This approach considers the psychological theories of work motivation (e.g., Steers and Mowday, 1977; Vroom, 1964); thus this "motivational" approach draws primarily from organizational psychology as a discipline base.

A related trend following later in time but somewhat comparable in content is the sociotechnical approach (Emory and Trist, 1960; Pasmore, 1988; Rousseau,

1977). It focuses not only on the work but also on the technology itself and the relationship of the environment to work and organizational design. Interest is less on the job and more on roles and systems. Keys to this approach are work system and job designs that fit their external environment and the joint optimization of both social and technical systems in the organization's internal environment. Though this approach differs somewhat in that consideration is also given to the technical system and external environment, it is similar in that it draws on the same psychological job characteristics that affect satisfaction and motivation. It suggests that as organizations' environments are becoming

*Mechanistic Approach*

1. Job specialization: The job is highly specialized in terms of purpose, tasks, or activities.  1 2 3 4 5
2. Specialization of tools and procedures: The tools, procedures, materials, etc., used on this job are highly specialized in terms of purpose.  1 2 3 4 5
3. Task simplification: The tasks are simple and uncomplicated.  1 2 3 4 5
4. Single activities: The job requires you to do only one task or activity at a time.  1 2 3 4 5
5. Skill simplification: The job requires relatively little skill and training time.  1 2 3 4 5
6. Repetition: The job requires performing the same activity(s) repeatedly.  1 2 3 4 5
7. Spare time: There is very little spare time between activities on this job.  1 2 3 4 5
8. Automation: Many of the activities of this job are automated or assisted by automation.  1 2 3 4 5

*Motivational Approach*

9. Autonomy: The job allows freedom, independence, or discretion in work scheduling, sequence, methods, procedures, quality control, or other decision making.  1 2 3 4 5
10. Intrinsic job feedback: The work activities themselves provide direct and clear information as to the effectiveness (e.g., quality and quantity) of job performance.  1 2 3 4 5
11. Extrinsic job feedback: Other people in the organization, such as managers and co-workers, provide information as to the effectiveness (e.g., quality and quantity) of job performance.  1 2 3 4 5
12. Social interaction: The job provides for positive social interaction such as team work or co-worker assistance.  1 2 3 4 5
13. Task/goal clarity: The job duties, requirements, and goals are clear and specific.  1 2 3 4 5
14. Task variety: The job has a variety of duties, tasks, and activities.  1 2 3 4 5
15. Task identity: The job requires completion of a whole and identifiable piece of work. It gives you a chance to do an entire piece of work from beginning to end.  1 2 3 4 5
16. Ability/skill-level requirements: The job requires a high level of knowledge, skills, and abilities.  1 2 3 4 5
17. Ability/skill variety: The job requires a variety of knowledge, skills, and abilities.  1 2 3 4 5
18. Task significance: The job is significant and important compared with other jobs in the organization.  1 2 3 4 5
19. Growth/learning: The job allows opportunities for learning and growth in competence and proficiency.  1 2 3 4 5
20. Promotion: There are opportunities for advancement to higher level jobs.  1 2 3 4 5
21. Achievement: The job provides for feelings of achievement and task accomplishment.  1 2 3 4 5
22. Participation: The job allows participation in work-related decision making.  1 2 3 4 5
23. Communication: The job has access to relevant communication channels and information flows.  1 2 3 4 5
24. Pay adequacy: The pay on this job is adequate compared with the job requirements and with the pay in similar jobs.  1 2 3 4 5
25. Recognition: The job provides acknowledgment and recognition from others.  1 2 3 4 5
26. Job security: People on this job have high job security.  1 2 3 4 5

*Perceptual/Motor Approach*

27. Lighting: The lighting in the workplace is adequate and free from glare.  1 2 3 4 5
28. Displays: The displays, gauges, meters, and computerized equipment on this job are easy to read and understand.  1 2 3 4 5
29. Programs: The programs in the computerized equipment on this job are easy to learn and use.  1 2 3 4 5
30. Other equipment: The other equipment (all types) used on this job is easy to learn and use.  1 2 3 4 5

**Table 2  (*continued*)**

| | | | | | | |
|---|---|---|---|---|---|---|
| 31. | Printed job materials: The printed materials used on this job are easy to read and interpret. | 1 | 2 | 3 | 4 | 5 |
| 32. | Workplace layout: The workplace is laid out such that you can see and hear well to perform the job. | 1 | 2 | 3 | 4 | 5 |
| 33. | Information input requirements: The amount of information you must attend to in order to perform this job is fairly minimal. | 1 | 2 | 3 | 4 | 5 |
| 34. | Information output requirements: The amount of information you must output on this job, in terms of both action and communication, is fairly minimal. | 1 | 2 | 3 | 4 | 5 |
| 35. | Information-processing requirements: The amount of information you must process, in terms of thinking and problem solving, is fairly minimal. | 1 | 2 | 3 | 4 | 5 |
| 36. | Memory requirements: The amount of information you must remember on this job is fairly minimal. | 1 | 2 | 3 | 4 | 5 |
| 37. | Stress: There is relatively little stress on this job. | 1 | 2 | 3 | 4 | 5 |

*Biological Approach*

| | | | | | | |
|---|---|---|---|---|---|---|
| 38. | Strength: The job requires fairly little muscular strength. | 1 | 2 | 3 | 4 | 5 |
| 39. | Lifting: The job requires fairly little lifting and/or the lifting is of very light weights. | 1 | 2 | 3 | 4 | 5 |
| 40. | Endurance: The job requires fairly little muscular endurance. | 1 | 2 | 3 | 4 | 5 |
| 41. | Seating: The seating arrangements on the job are adequate (e.g., ample opportunities to sit, comfortable chairs, good postural support). | 1 | 2 | 3 | 4 | 5 |
| 42. | Size differences: The workplace allows for all size differences between people in terms of clearance, reach, eye height, leg room, etc. | 1 | 2 | 3 | 4 | 5 |
| 43. | Wrist movement: The job allows the wrists to remain straight without excessive movement. | 1 | 2 | 3 | 4 | 5 |
| 44. | Noise: The workplace is free from excessive noise. | 1 | 2 | 3 | 4 | 5 |
| 45. | Climate: The climate at the workplace is comfortable in terms of temperature and humidity, and it is free of excessive dust and fumes. | 1 | 2 | 3 | 4 | 5 |
| 46. | Work breaks: There is adequate time for work breaks given the demands of the job. | 1 | 2 | 3 | 4 | 5 |
| 47. | Shift work: The job does not require shift work or excessive overtime. | 1 | 2 | 3 | 4 | 5 |

*For jobs with little physical activity due to single work station add:*

| | | | | | | |
|---|---|---|---|---|---|---|
| 48. | Exercise opportunities: During the day, there are enough opportunities to get up from the work station and walk around. | 1 | 2 | 3 | 4 | 5 |
| 49. | Constraint: While at the work station, the worker is not constrained to a single position. | 1 | 2 | 3 | 4 | 5 |
| 50. | Furniture: At the work station, the worker can adjust or arrange the furniture to be comfortable (e.g., adequate legroom, foot rests if needed, proper keyboard or work surface height). | 1 | 2 | 3 | 4 | 5 |

*Source*: Table adapted from Campion (1988). See supporting references and related research (e.g., Campion and McClelland, 1991, 1993; Campion and Thayer, 1985) for reliability and validity information. Scores for each approach are calculated by averaging applicable items.

increasingly turbulent and complex, organizational and job design should involve greater flexibility, employee involvement, employee training, and decentralization of decision making and control, and a reduction in hierarchical structures and the formalization of procedures and relationships (Pasmore, 1988).

Surveys of industrial job designers have consistently indicated that the mechanistic approach represents the dominant theme of job design (Davis et al., 1955; Taylor, 1979). Other approaches to job design, such as the motivational approach, have not been given as much explicit consideration. This is not surprising because the surveys only included job designers trained in engineering-related disciplines, such as industrial engineering and systems analysis. It is not necessarily certain that other specialists or line managers would adopt the same philosophies, especially in recent times. Nevertheless, there is evidence that even fairly naive job designers (i.e., college students in management classes) also adopt the mechanistic approach in job

design simulations. That is, their strategies for grouping tasks were primarily based on such factors as activities, skills, equipment, procedures, or location. Even though the mechanistic approach may be the most natural and intuitive, this research has also revealed that people can be trained to apply all four approaches to job design (Campion and Stevens, 1991). The motivational characteristics of the WDQ are an extension of this motivational approach to job design. This set of characteristics is based on the idea that high levels of these characteristics make work more motivating, satisfying, and enriching. Subcategories of these characteristics include task characteristics (task variety, task significance, task identity, and feedback from the job) and knowledge characteristics (job complexity, information processing, problem solving, skill variety, and specialization).

Building off of the ideas presented in Morgeson and Humphrey's WDQ, scholars are beginning to examine the social aspects of work design and how they interact

### Task Characteristics

*Autonomy/Work Scheduling Autonomy*

1. The job allows me to make my own decisions about how to schedule my work.    1 2 3 4 5
2. The job allows me to decide on the order in which things are done on the job.    1 2 3 4 5
3. The job allows me to plan how I do my work.    1 2 3 4 5

*Autonomy/Decision-Making Autonomy*

4. The job gives me a chance to use my personal initiative or judgment in carrying out the work.    1 2 3 4 5
5. The job allows me to make a lot of decisions on my own.    1 2 3 4 5
6. The job provides me with significant autonomy in making decisions.    1 2 3 4 5

*Autonomy/Work Methods Autonomy*

7. The job allows me to make decisions about what methods I use to complete my work.    1 2 3 4 5
8. The job gives me considerable opportunity for independence and freedom in how I do the work.    1 2 3 4 5
9. The job allows me to decide on my own how to go about doing my work.    1 2 3 4 5

*Task Variety*

10. The job involves a great deal of task variety.    1 2 3 4 5
11. The job involves doing a number of different things.    1 2 3 4 5
12. The job requires the performance of a wide range of tasks.    1 2 3 4 5
13. The job involves performing a variety of tasks.    1 2 3 4 5

*Task Significance*

14. The results of my work are likely to significantly affect the lives of other people.    1 2 3 4 5
15. The job itself is very significant and important in the broader scheme of things.    1 2 3 4 5
16. The job has a large impact on people outside the organization.    1 2 3 4 5
17. The work performed on the job has a significant impact on people outside the organization.    1 2 3 4 5

*Task Identity*

18. The job involves completing a piece of work that has an obvious beginning and end.    1 2 3 4 5
19. The job is arranged so that I can do an entire piece of work from beginning to end.    1 2 3 4 5
20. The job provides me the chance to completely finish the pieces of work I begin.    1 2 3 4 5
21. The job allows me to complete work I start.    1 2 3 4 5

*Feedback from Job*

22. The work activities themselves provide direct and clear information about the effectiveness (e.g., quality and quantity) of my job performance.    1 2 3 4 5
23. The job itself provides feedback on my performance.    1 2 3 4 5
24. The job itself provides me with information about my performance.    1 2 3 4 5

### Knowledge Characteristics

*Job Complexity*

25. The job requires that I only do one task or activity at a time (reverse scored).    1 2 3 4 5
26. The tasks on the job are simple and uncomplicated (reverse scored).    1 2 3 4 5
27. The job comprises relatively uncomplicated tasks (reverse scored).    1 2 3 4 5
28. The job involves performing relatively simple tasks (reverse scored).    1 2 3 4 5

**Table 3** (*continued*)

*Information Processing*

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| 29. | The job requires me to monitor a great deal of information. | 1 | 2 | 3 | 4 | 5 |
| 30. | The job requires that I engage in a large amount of thinking. | 1 | 2 | 3 | 4 | 5 |
| 31. | The job requires me to keep track of more than one thing at a time. | 1 | 2 | 3 | 4 | 5 |
| 32. | The job requires me to analyze a lot of information. | 1 | 2 | 3 | 4 | 5 |

*Problem Solving*

| | | | | | | |
|---|---|---|---|---|---|---|
| 33. | The job involves solving problems that have no obvious correct answer. | 1 | 2 | 3 | 4 | 5 |
| 34. | The job requires me to be creative. | 1 | 2 | 3 | 4 | 5 |
| 35. | The job often involves dealing with problems that I have not met before. | 1 | 2 | 3 | 4 | 5 |
| 36. | The job requires unique ideas or solutions to problems. | 1 | 2 | 3 | 4 | 5 |

*Skill Variety*

| | | | | | | |
|---|---|---|---|---|---|---|
| 37. | The job requires a variety of skills. | 1 | 2 | 3 | 4 | 5 |
| 38. | The job requires me to utilize a variety of different skills in order to complete the work. | 1 | 2 | 3 | 4 | 5 |
| 39. | The job requires me to use a number of complex or high-level skills. | 1 | 2 | 3 | 4 | 5 |
| 40. | The job requires the use of a number of skills. | 1 | 2 | 3 | 4 | 5 |

*Specialization*

| | | | | | | |
|---|---|---|---|---|---|---|
| 41. | The job is highly specialized in terms of purpose, tasks, or activities. | 1 | 2 | 3 | 4 | 5 |
| 42. | The tools, procedures, materials, and so forth used on this job are highly specialized in terms of purpose. | 1 | 2 | 3 | 4 | 5 |
| 43. | The job requires very specialized knowledge and skills. | 1 | 2 | 3 | 4 | 5 |
| 44. | The job requires a depth of knowledge and expertise. | 1 | 2 | 3 | 4 | 5 |

### Social Characteristics

*Social Support*

| | | | | | | |
|---|---|---|---|---|---|---|
| 45. | I have the opportunity to develop close friendships in my job. | 1 | 2 | 3 | 4 | 5 |
| 46. | I have the chance in my job to get to know other people. | 1 | 2 | 3 | 4 | 5 |
| 47. | I have the opportunity to meet with others in my work. | 1 | 2 | 3 | 4 | 5 |
| 48. | My supervisor is concerned about the welfare of the people that work for him/her. | 1 | 2 | 3 | 4 | 5 |
| 49. | People I work with take a personal interest in me. | 1 | 2 | 3 | 4 | 5 |
| 50. | People I work with are friendly. | 1 | 2 | 3 | 4 | 5 |

*Interdependence/Initiated Interdependence*

| | | | | | | |
|---|---|---|---|---|---|---|
| 51. | The job requires me to accomplish my job before others complete their jobs. | 1 | 2 | 3 | 4 | 5 |
| 52. | Other jobs depend directly on my job. | 1 | 2 | 3 | 4 | 5 |
| 53. | Unless my job gets done, other jobs cannot be completed. | 1 | 2 | 3 | 4 | 5 |

*Interdependence/Received Interdependence*

| | | | | | | |
|---|---|---|---|---|---|---|
| 54. | The job activities are greatly affected by the work of other people. | 1 | 2 | 3 | 4 | 5 |
| 55. | The job depends on the work of many different people for its completion. | 1 | 2 | 3 | 4 | 5 |
| 56. | My job cannot be done unless others do their work. | 1 | 2 | 3 | 4 | 5 |

*Interaction Outside Organization*

| | | | | | | |
|---|---|---|---|---|---|---|
| 57. | The job requires spending a great deal of time with people outside my organization. | 1 | 2 | 3 | 4 | 5 |
| 58. | The job involves interaction with people who are not members of my organization. | 1 | 2 | 3 | 4 | 5 |
| 59. | On the job, I frequently communicate with people who do not work for the same organization as I do. | 1 | 2 | 3 | 4 | 5 |
| 60. | The job involves a great deal of interaction with people outside my organization. | 1 | 2 | 3 | 4 | 5 |

*Feedback from Others*

| | | | | | | |
|---|---|---|---|---|---|---|
| 61. | I receive a great deal of information from my manager and co-workers about my job performance. | 1 | 2 | 3 | 4 | 5 |
| 62. | Other people in the organization, such as managers and co-workers, provide information about the effectiveness (e.g., quality and quantity) of my job performance. | 1 | 2 | 3 | 4 | 5 |
| 63. | I receive feedback on my performance from other people in my organization (such as my manager or co-workers). | 1 | 2 | 3 | 4 | 5 |

with the peoples' on the job experience (Humphrey et al., 2007; Grant and Parker, 2009; Grant, 2007, 2008). Social characteristics consider the broader social environment in which the work is done as a component of workers' job experience. Social characteristics include social support (broadly refers to the support employees receive from others at work), interdependence (the interconnections of the tasks, sequencing, and impact of an employee's job with the jobs of others), interaction outside the organization, and feedback from others. Some of these social characteristics were originally encompassed within the motivational approach to job design (e.g., interdependence and feedback from others). By separating the social work characteristics from the task and knowledge characteristics, the WDQ allows job designers to focus specifically on the design of the interpersonal aspects of the work. Managers often have to address these aspects of work design in a different manner than they do with task and knowledge aspects. Subsequent meta-analytic evidence suggests that social characteristics addressed in the WDQ explain incremental variance above and beyond that explained by motivational characteristics (Humphrey et al., 2007).

### 2.2.2 Design Recommendations

Table 2 provides a list of statements that describe recommendations for the motivational approach. It suggests a job should allow a worker autonomy to make decisions about how and when tasks are to be done. A worker should feel his or her work is important to the overall mission of the organization or department. This

is often done by allowing a worker to perform a larger unit of work or to perform an entire piece of work from beginning to end. Feedback on job performance should be given to workers from the task itself as well as from the supervisor and others. Workers should be able to use a variety of skills and to personally grow on the job. This approach also considers the social, or people/interaction, aspects of the job; jobs should have opportunities for participation, communication, and recognition. Finally, other human resource systems should contribute to the motivating atmosphere, such as adequate pay, promotion, and job security systems.

### 2.2.3 Advantages and Disadvantages

The goal of this approach is to enhance psychological meaningfulness of jobs, thus influencing a variety of attitudinal and behavioral outcomes. Table 1 summarizes some of the advantages and disadvantages found in research. Jobs designed according to the motivational approach have more satisfied, motivated, and involved employees who tend to have higher performance and lower absenteeism. Customer service may be improved, because employees take more pride in work and can catch their own errors by performing a larger part of the work. Social impact, social worth, and mere social contact have been shown to have a positive influence on workers' performance (Grant, 2008; Grant et al., 2007). In a field experiment with community recreation center lifeguards, Grant (2008) demonstrated that task significance operated through their perceptions of social impact and social worth to influence job dedication and helping behavior. As an answer to the rapidly

changing nature of work, researchers have begun to study work design characteristics that could stimulate employee proactivity. While some characteristics are already embedded within the current models of job design, the approach has led to a few additional characteristics that could prove beneficial in a dynamic work environment. Specifically, both ambiguity and accountability have been suggested to influence employees' proactive behaviors (Grant and Parker, 2009; Staw and Boettger, 1990). In terms of disadvantages, jobs too high on the motivational approach require more training, have greater skill and ability requirements for staffing, and may require higher compensation. Overly motivating jobs may also be so stimulating that workers become predisposed to mental overload, fatigue, errors, and occupational stress.

## 2.3 Perceptual/Motor Job Design Approach

### 2.3.1 Historical Development

This approach draws on a scientific discipline which goes by many names, including human factors, human factors engineering, human engineering, man–machine systems engineering, and engineering psychology. It developed from a number of other disciplines, primarily experimental psychology, but also industrial engineering (Meister, 1971). Within experimental psychology, job design recommendations draw heavily from knowledge of human skilled performance (Welford, 1976) and the analysis of humans as information processors (see Chapters 2.4). The main concern of this approach is efficient and safe utilization of humans in human–machine systems, with emphasis on selection, design, and arrangement of system components to take account of both human abilities and limitations (Pearson, 1971). It is more concerned with equipment than psychology and with human abilities than engineering.

This approach received public attention with the Three Mile Island incident where it was concluded that the control room operator job in the nuclear power plant may have placed too many demands on the operator in an emergency situation, thus predisposing errors of judgment (Campion and Thayer, 1987). Government regulations issued since then require nuclear plants to consider "human factors" in their design (U.S. Nuclear Regulatory Commission, 1981). The primary emphasis of this approach is on perceptual and motor abilities of people. (See Chapters 20–22 for more information on equipment design).

The contextual characteristics of the WDQ reflect the physical and environmental contexts within which work is performed. This was an aspect initially described in the MJDQ and subsequently elaborated upon in the WDQ. Many of the contextual characteristics of job design encompass the perceptual–motor and biological/physiological (described in Section 2.4) approaches to job design as addressed in the MJDQ. Contextual characteristics include ergonomics, physical demands, work conditions, and equipment use. The WDQ's discrimination between contextual characteristics and other forms of motivational characteristics (i.e., task, knowledge, and social characteristics) allows managers to

focus specifically on the aspects of work that can produce worker strain or hazardous working conditions while still assessing the motivating aspects of the work. Meta-analytic evidence suggests that the contextual work characteristics addressed in the WDQ explain incremental variance above and beyond that explained by the motivational characteristics (Humphrey et al., 2007).

### 2.3.2 Design Recommendations

Table 2 provides a list of statements describing important recommendations of the perceptual/motor approach. They refer to either the equipment or environment and to information-processing requirements. Their thrust is to consider mental abilities and limitations of humans such that the attention and concentration requirements of the job do not exceed the abilities of the least capable potential worker. Focus is on the limits of the least capable worker because this approach is concerned with the effectiveness of the total system, which is no better than its "weakest link." Jobs should be designed to limit the amount of information workers must pay attention to and remember. Lighting levels should be appropriate, displays and controls should be logical and clear, workplaces should be well laid out and safe, and equipment should be easy to use. (See Chapters 56–61 for more information on human factors applications.)

### 2.3.3 Advantages and Disadvantages

The goals of this approach are to enhance reliability, safety, and positive user reactions. Table 1 summarizes advantages and disadvantages found in research. Jobs designed according to the perceptual/motor approach have lower errors and accidents. Like the mechanistic approach, it reduces mental ability requirements of the job; thus employees may be less stressed and mentally fatigued. It may also create some efficiencies, such as reduced training time and staffing requirements. On the other hand, costs from the excessive use of the perceptual/motor approach can include low satisfaction, low motivation, and boredom due to inadequate mental stimulation. This problem is exacerbated by the fact that designs based on the least capable worker essentially lower a job's mental requirements.

## 2.4 Biological Job Design Approach

### 2.4.1 Historical Development

This approach and the perceptual/motor approach share a joint concern for proper person–machine fit. The major difference is that this approach is more oriented toward biological considerations and stems from such disciplines as work physiology (see Chapter 10), biomechanics (i.e., study of body movements, see Chapter 9), and anthropometry (i.e., study of body sizes, see Chapters 8 and 23). Although many specialists probably practice both approaches together, as is reflected in many texts in the area (Konz, 1983), a split does exist between Americans who are more psychologically oriented and use the title "human factors engineer" and Europeans who are more physiologically oriented and use the title "ergonomist" (Chapanis, 1970). Like the

perceptual–motor approach, the biological approach is concerned with the design of equipment and workplaces as well as the design of tasks (Grandjean, 1980).

### 2.4.2 Design Recommendations

Table 2 lists important recommendations from the biological approach. This approach tries to design jobs to reduce physical demands to avoid exceeding people's physical capabilities and limitations. Jobs should not require excessive strength and lifting, and, again, abilities of the least physically able potential worker set the maximum level. Chairs should be designed for good postural support. Excessive wrist movement should be reduced by redesigning tasks and equipment. Noise, temperature, and atmosphere should be controlled within reasonable limits. Proper work–rest schedules should be provided so employees can recuperate from the physical demands.

### 2.4.3 Advantages and Disadvantages

The goals of this approach are to maintain employees' comfort and physical well-being. Table 1 summarizes some advantages and disadvantages observed in research. Jobs designed according to this approach require less physical effort, result in less fatigue, and create fewer injuries and aches and pains than jobs low on this approach. Occupational illnesses, such as lower back pain and carpal tunnel syndrome, are fewer on jobs designed with this approach. There may be lower absenteeism and higher job satisfaction on jobs which are not physically arduous. However, a direct cost of this approach may be the expense of changes in equipment or job environments needed to implement the recommendations. At the extreme, costs may include jobs with so few physical demands that workers become drowsy or lethargic, thus reducing performance. Clearly, extremes of physical activity and inactivity should be avoided, and an optimal level of physical activity should be developed.

## 3 TEAM DESIGN APPROACH

### 3.1 Historical Development

An alternative to designing work around individual jobs is to design work for teams of workers. Teams can vary a great deal in how they are designed and can conceivably incorporate elements from any of the job design approaches discussed. However, the focus here is on the self-managing, autonomous type of team design approach, which is gaining considerable popularity in organizations and substantial research attention today (Guzzo and Shea, 1992; Hoerr, 1989; Ilgen et al., 2005; Sundstrom et al., 1990; Swezey and Salas, 1992; Campion et al., 1996; Parker, 2003; LePine et al., 2008). Autonomous work teams derive their conceptual basis from motivational job design and from sociotechnical systems theory, which in turn reflect social and organizational psychology and organizational behavior (Cummings, 1978; Davis, 1971; Davis and Valfer, 1965; Morgeson and Campion, 2003). The Hawthorne studies (Homans, 1950) and European experiments with autonomous work groups (Kelly, 1982; Pasmore

et al., 1982) called attention to the benefits of applying work teams in situations other than sports and military settings. Although enthusiasm for the use of teams had waned in the 1960s and 1970s due to research discovering some disadvantages of teams (Buys, 1978; Zander, 1979), the 1980s brought a resurgence of interest in the use of work teams and it has become an extremely popular work design in organizations today (Hackman, 2002; Hoerr, 1989; Ilgen et al., 2005; Sundstrom et al., 1990). This renewed interest may be due to the cost advantages of having fewer supervisors with self-managed teams or the apparent logic of the benefits of teamwork.

### 3.2 Design Recommendations

Teams can vary in the degree of authority and autonomy they have (Banker et al., 1996). For example, manager-led teams have responsibility only for the execution of their work. Management designs the work, designs the teams, and provides an organizational context for the teams. However, in autonomous work teams, or self-managing teams, team members design and monitor their own work and performance. They may also design their own team structure (e.g., delineating interrelationships among members) and composition (e.g., selecting members). In such self-designing teams, management is only responsible for the teams' organizational context (Hackman, 1987). Although team design could incorporate elements of either mechanistic or motivational approaches to design, narrow and simplistic mechanistically designed jobs would be less consistent with other suggested aspects of the team approach to design than motivationally designed jobs. Mechanistically designed jobs would not allow an organization to gain as much of the advantages from placing workers in teams.

Figure 1 and Table 4 provide important recommendations from the self-managing team design approach. Many of the advantages of work teams depend on how teams are designed and supported by their organization. According to the theory behind self-managing team design, decision making and responsibility should be pushed down to the team members (Hackman, 1987). If management is willing to follow this philosophy, teams can provide several additional advantages. By pushing decision making down to the team and requiring consensus, the organization will find greater acceptance, understanding, and ownership of decisions (Porter et al., 1987). The perceived autonomy resulting from making work decisions should be both satisfying and motivating. Thus, this approach tries to design teams so they have a high degree of self-management and all team members participate in decision making.

The team design approach also suggests that the set of tasks assigned to a team should provide a whole and meaningful piece of work (i.e., have task identity as in the motivational approach to job design). This allows team members to see how their work contributes to a whole product or process, which might not be possible with individuals working alone. This can give workers a better idea of the significance of their work and create greater identification with the finished product or service. If team workers rotate among a variety of subtasks and cross-train on different operations,

**Themes/characteristics**                    **Effectiveness criteria**

**Job design**
- Self-management
- Participation
- Task variety
- Task significance
- Task identity

**Interdependence**
- Task interdependence
- Goal interdependence
- Interdependent feedback and rewards

**Composition**
- Heterogeneity
- Flexibility
- Relative size
- Preference for teamwork

**Context**
- Training
- Managerial support
- Communication/cooperation between teams

**Process**
- Potency
- Social support
- Workload sharing
- Communication/cooperation within the team

Productivity

Satisfaction

Manager judgments

**Figure 1** Characteristics related to team effectiveness.

workers should also perceive greater variety in the work (Campion et al., 1994b).

Interdependent tasks, goals, feedback, and rewards should be provided to create feelings of team interdependence among members and focus on the team as the unit of performance, rather than on the individual. It is suggested that team members should be heterogeneous in terms of areas of expertise and background so their varied knowledge, skills, and abilities (KSAs) complement one another. Teams also need adequate training, managerial support, and organizational resources to carry out their tasks. Managers should encourage positive group processes including open communication and cooperation within and between work groups, supportiveness and sharing of the workload among team members, and development of positive team spirit and confidence in the team's ability to perform effectively.

### 3.3 Advantages and Disadvantages

Table 5 summarizes advantages and disadvantages of team design relative to individual job design. To begin with, teams designed so members have heterogeneity of KSAs can help team members learn by working with others who have different KSAs. Cross-training on different tasks can occur, and the workforce can become more flexible (Goodman et al., 1986). Teams with heterogeneous KSAs also allow for synergistic combinations of ideas and abilities not possible with individuals working alone, and such teams have generally shown higher performance, especially when task requirements are diverse (Goodman et al., 1986; Shaw, 1983).

Social support can be especially important when teams face difficult decisions and deal with difficult psychological aspects of tasks, such as in military

**Table 4 Team Design Measure**

*Instructions:* This questionnaire consists of statements about your team and how your team functions as a group. Please indicate the extent to which each statement describes your team by circling a number to the right of each statement.

*Please use the following scale*:

| | |
|---|---|
| **(5)** | Strongly agree |
| **(4)** | Agree |
| **(3)** | Neither agree nor disagree |
| **(2)** | Disagree |
| **(1)** | Strongly disagree |
| **( )** | Leave blank if do not know or not applicable |

*Self-Management*

1. The members of my team are responsible for determining the methods, procedures, and schedules with which the work gets done.    1 2 3 4 5
2. My team rather than my manager decides who does what tasks within the team.    1 2 3 4 5
3. Most work-related decisions are made by the members of my team rather than by my manager.    1 2 3 4 5

*Participation*

4. As a member of a team, I have a real say in how the team carries out its work.    1 2 3 4 5
5. Most members of my team get a chance to participate in decision making.    1 2 3 4 5
6. My team is designed to let everyone participate in decision making.    1 2 3 4 5

*Task Variety*

7. Most members of my team get a chance to learn the different tasks the team performs.    1 2 3 4 5
8. Most everyone on my team gets a chance to do the more interesting tasks.    1 2 3 4 5
9. Task assignments often change from day to day to meet the workload needs of the team.    1 2 3 4 5

*Task Significance (Importance)*

10. The work performed by my team is important to the customers in my area.    1 2 3 4 5
11. My team makes an important contribution to serving the company's customers.    1 2 3 4 5
12. My team helps me feel that my work is important to the company.    1 2 3 4 5

*Task Identity (Mission)*

13. The team concept allows all the work on a given product to be completed by the same set of people.    1 2 3 4 5
14. My team is responsible for all aspects of a product for its area.    1 2 3 4 5
15. My team is responsible for its own unique area or segment of the business.    1 2 3 4 5

*Task Interdependence (Interdependence)*

16. I cannot accomplish my tasks without information or materials from other members of my team.    1 2 3 4 5
17. Other members of my team depend on me for information or materials needed to perform their tasks.    1 2 3 4 5
18. Within my team, jobs performed by team members are related to one another.    1 2 3 4 5

*Goal Interdependence (Goals)*

19. My work goals come directly from the goals of my team.    1 2 3 4 5
20. My work activities on any given day are determined by my team's goals for that day.    1 2 3 4 5
21. I do very few activities on my job that are not related to the goals of my team.    1 2 3 4 5

*Interdependent Feedback and Rewards (Feedback and Rewards)*

22. Feedback about how well I am doing my job comes primarily from information about how well the entire team is doing.    1 2 3 4 5
23. My performance evaluation is strongly influenced by how well my team performs.    1 2 3 4 5
24. Many rewards from my job (pay, promotion, etc.) are determined in large part by my contributions as a team member.    1 2 3 4 5

*(continued overleaf)*

**Table 4  (*continued*)**

| | *Heterogeneity (Membership)* | | | | | |
|---|---|---|---|---|---|---|
| 25. | The members of my team vary widely in their areas of expertise. | 1 | 2 | 3 | 4 | 5 |
| 26. | The members of my team have a variety of different backgrounds and experiences. | 1 | 2 | 3 | 4 | 5 |
| 27. | The members of my team have skills and abilities that complement each other. | 1 | 2 | 3 | 4 | 5 |
| | *Flexibility (Member Flexibility)* | | | | | |
| 28. | Most members of my team know each other's jobs. | 1 | 2 | 3 | 4 | 5 |
| 29. | It is easy for the members of my team to fill in for one another. | 1 | 2 | 3 | 4 | 5 |
| 30. | My team is very flexible in terms of membership. | 1 | 2 | 3 | 4 | 5 |
| | *Relative Size (Size)* | | | | | |
| 31. | The number of people in my team is too small for the work to be accomplished. (Reverse scored) | 1 | 2 | 3 | 4 | 5 |
| | *Preference for Team Work (Team Work Preferences)* | | | | | |
| 32. | If given the choice, I would prefer to work as part of a team rather than work alone. | 1 | 2 | 3 | 4 | 5 |
| 33. | I find that working as a member of a team increases my ability to perform effectively. | 1 | 2 | 3 | 4 | 5 |
| 34. | I generally prefer to work as part of a team. | 1 | 2 | 3 | 4 | 5 |
| | *Training* | | | | | |
| 35. | The company provides adequate technical training for my team. | 1 | 2 | 3 | 4 | 5 |
| 36. | The company provides adequate quality and customer service training for my team. | 1 | 2 | 3 | 4 | 5 |
| 37. | The company provides adequate team skills training for my team (communication, organization, interpersonal, etc.). | 1 | 2 | 3 | 4 | 5 |
| | *Managerial Support* | | | | | |
| 38. | Higher management in the company supports the concept of teams. | 1 | 2 | 3 | 4 | 5 |
| 39. | My manager supports the concept of teams. | 1 | 2 | 3 | 4 | 5 |
| | *Communication/Cooperation between Work Groups* | | | | | |
| 40. | I frequently talk to other people in the company besides the people on my team. | 1 | 2 | 3 | 4 | 5 |
| 41. | There is little competition between my team and other teams in the company. | 1 | 2 | 3 | 4 | 5 |
| 42. | Teams in the company cooperate to get the work done. | 1 | 2 | 3 | 4 | 5 |
| | *Potency (Spirit)* | | | | | |
| 43. | Members of my team have great confidence that the team can perform effectively. | 1 | 2 | 3 | 4 | 5 |
| 44. | My team can take on nearly any task and complete it. | 1 | 2 | 3 | 4 | 5 |
| 45. | My team has a lot of team spirit. | 1 | 2 | 3 | 4 | 5 |
| | *Social Support* | | | | | |
| 46. | Being in my team gives me the opportunity to work in a team and provide support to other team members. | 1 | 2 | 3 | 4 | 5 |
| 47. | My team increases my opportunities for positive social interaction. | 1 | 2 | 3 | 4 | 5 |
| 48. | Members of my team help each other out at work when needed. | 1 | 2 | 3 | 4 | 5 |
| | *Workload Sharing (Sharing the Work)* | | | | | |
| 49. | Everyone on my team does their fair share of the work. | 1 | 2 | 3 | 4 | 5 |
| 50. | No one in my team depends on other team members to do the work for them. | 1 | 2 | 3 | 4 | 5 |
| 51. | Nearly all the members of my team contribute equally to the work. | 1 | 2 | 3 | 4 | 5 |
| | *Communication/Cooperation within the Work Group* | | | | | |
| 52. | Members of my team are very willing to share information with other team members about our work. | 1 | 2 | 3 | 4 | 5 |
| 53. | Teams enhance the communications among people working on the same product. | 1 | 2 | 3 | 4 | 5 |
| 54. | Members of my team cooperate to get the work done. | 1 | 2 | 3 | 4 | 5 |

*Source*: Table adapted from Campion et al. (1993). See reference and related research (Campion et al., 1996) for reliability and validity information. Scores for each team characteristic are calculated by averaging applicable items.

**Table 5 Advantages and Disadvantages of Work Teams**

| Advantages | Disadvantages |
|---|---|
| • Team members learn from one another | • Lack of compatibility of some individuals with team work |
| • Possibility of greater workforce flexibility with cross-training | • Additional need to select workers to fit team as well as job |
| • Opportunity for synergistic combinations of ideas and abilities | • Possibility some members will experience less motivating jobs |
| • New approaches to tasks may be discovered | • Possible incompatibility with cultural, organizational, or labor–management norms |
| • Social facilitation and arousal | |
| • Social support for difficult tasks and situations | • Increased competition and conflict between teams |
| • Increased communication and information exchange between team members | • More time consuming due to socializing, coordination losses, and need for consensus |
| • Greater cooperation among team members | • Inhibition of creativity and decision-making processes; possibility of groupthink |
| • Beneficial for interdependent work flows | |
| • Greater acceptance and understanding of decisions when team makes decisions | • Less powerful evaluation and rewards; social loafing or free riding may occur |
| • Greater autonomy, variety, identity, significance, and feedback possible for workers | • Less flexibility in cases of replacement, turnover, or transfer |
| • Commitment to the team may stimulate performance and attendance | |

*Source*: Adapted from Campion and Medsker (1992).

squads, medical teams, or police units (Campion and Medsker, 1992). In addition, the simple presence of others can be psychologically arousing. Research has shown that such arousal can have a positive effect on performance when the task is well learned (Zajonc, 1965) and when other team members are perceived as evaluating the performer (Harkins, 1987; Porter et al., 1987). With routine jobs, this arousal effect may counteract boredom and performance decrements (Cartwright, 1968).

Another advantage of teams is that they can increase information exchanged between members through proximity and shared tasks (McGrath, 1984). Increased cooperation and communication within teams can be particularly useful when workers' jobs are highly interrelated, such as when workers whose tasks come later in the process must depend on the performance of workers whose tasks come earlier or when workers exchange work back and forth among themselves (Mintzberg, 1979; Thompson, 1967).

In addition, if teams are rewarded for team effort, rather than individual effort, members will have an incentive to cooperate with one another (Leventhal, 1976). The desire to maintain power by controlling information may be reduced. More experienced workers may be more willing to train the less experienced when they are not in competition with them. Team design and rewards can also be helpful in situations where it is difficult to measure individual performance or where workers mistrust supervisors' assessments of performance (Milkovich and Newman, 1993).

Finally, teams can be beneficial if team members develop a feeling of commitment and loyalty to their team (Cartwright, 1968). For workers who do not develop high commitment to their organization or management and who do not become highly involved in their job, work teams can provide a source of commitment. That is, members may feel responsible to attend work, cooperate with others, and perform well because of commitment to their work team, even though they are not strongly committed to the organization or the work itself.

Thus, designing work around teams can provide several advantages to organizations and their workers. Unfortunately, there are also disadvantages to using work teams and situations in which individual-level design is preferable to team design. For example, some individuals may dislike team work and may not have necessary interpersonal skills or desire to work in a team. When selecting team members, one has the additional requirement of selecting workers to fit the team as well as the job. (Section 4.3 provides more information on the selection of team members; see also Chapter 16 for general information on personnel selection.)

Individuals can experience less autonomy and less personal identification when working on a team. Designing work around teams does not guarantee workers greater variety, significance, and identity. If members within the team do not rotate among tasks or if some members are assigned exclusively to less desirable tasks, not all members will benefit from team design. Members can still have fractionated, demotivating jobs.

Team work can also be incompatible with cultural norms. The United States has a very individualistic culture (Hofstede, 1980). Applying team methods that have been successful in collectivistic societies like Japan may be problematic in the United States. In addition,

organizational norms and labor–management relations may be incompatible with team design, making its use more difficult.

Some advantages of team design can create disadvantages as well. First, though team rewards can increase communication and cooperation and reduce competition within a team, they may cause greater competition and reduced communication between teams. If members identify too strongly with a team, they may not realize when behaviors that benefit the team detract from organizational goals and create conflicts detrimental to productivity. Increased communication within teams may not always be task relevant either. Teams may spend work time socializing. Team decision making can take longer than individual decision making, and the need for coordination within teams can be time consuming.

Decision making and creativity can also be inhibited by team processes. When teams become highly cohesive, they may become so alike in their views that they develop "groupthink" (Janis, 1972). When groupthink occurs, teams tend to underestimate their competition, fail to adequately critique fellow team members' suggestions, not appraise alternatives adequately, and fail to work out contingency plans. In addition, team pressures distort judgments. Decisions may be based more on persuasiveness of dominant individuals or the power of majorities, rather than on the quality of decisions. Research has found a tendency for team judgments to be more extreme than the average of individual members' predecision judgments (Janis, 1972; McGrath, 1984; Morgeson and Campion, 1997). Although evidence shows highly cohesive teams are more satisfied with their teams, cohesiveness is not necessarily related to high productivity. Whether cohesiveness is related to performance depends on a team's norms and goals. If a team's norm is to be productive, cohesiveness will enhance productivity; however, if the norm is not one of commitment to productivity, cohesiveness can have a negative influence (Zajonc, 1965).

The use of teams and team-level rewards can also decrease the motivating power of evaluation and reward systems. If team members are not evaluated for individual performance, do not believe their output can be distinguished from the team's, or do not perceive a link between their personal performance and outcomes, social loafing (Harkins, 1987) can occur. In such situations, teams do not perform up to the potential expected from combining individual efforts.

Finally, teams may be less flexible in some respects because they are more difficult to move or transfer as a unit than individuals (Sundstrom et al., 1990). Turnover, replacements, and employee transfers may disrupt teams. And members may not readily accept new members.

Thus, whether work teams are advantageous depends to a great extent on the composition, structure, reward systems, environment, and task of the team. Table 6 presents questions that can help determine whether work should be designed around teams rather than individuals.

**Table 6  When to Design Jobs around Work Teams**

| | |
|---|---|
| 1. | Are workers' tasks highly interdependent or could they be made to be so? Would this interdependence enhance efficiency or quality? |
| 2. | Do the tasks require a variety of knowledge, skills, abilities such that combining individuals with different backgrounds would make a difference in performance? |
| 3. | Is cross-training desired? Would breadth of skills and workforce flexibility be essential to the organization? |
| 4. | Could increased arousal, motivation, and effort to perform make a difference in effectiveness? |
| 5. | Can social support help workers deal with job stresses? |
| 6. | Could increased communication and information exchange improve performance rather than interfere? |
| 7. | Could increased cooperation aid performance? |
| 8. | Are individual evaluation and rewards difficult or impossible to make or are they mistrusted by workers? |
| 9. | Could common measures of performance be developed and used? |
| 10. | Is it technically possible to group tasks in a meaningful, efficient way? |
| 11. | Would individuals be willing to work in teams? |
| 12. | Does the labor force have the interpersonal skills needed to work in teams? |
| 13. | Would team members have the capacity and willingness to be trained in interpersonal and technical skills required for team work? |
| 14. | Would team work be compatible with cultural norms, organizational policies, and leadership styles? |
| 15. | Would labor-management relations be favorable to team job design? |
| 16. | Would the amount of time taken to reach decisions, consensus, and coordination not be detrimental to performance? |
| 17. | Can turnover be kept to a minimum? |
| 18. | Can teams be defined as a meaningful unit of the organization with identifiable inputs, outputs, and buffer areas which give them a separate identity from other teams? |
| 19. | Would members share common resources, facilities, or equipment? |
| 20. | Would top management support team job design? |

*Source*: Table adapted from Campion and Medsker (1992). Affirmative answers support the use of team job design.

The more questions answered in the affirmative, the more likely teams are to be beneficial. If one chooses to design work around teams, suggestions for designing effective teams are presented in Section 4.3.

## 4   IMPLEMENTATION ADVICE FOR JOB AND TEAM DESIGN

### 4.1   General Implementation Advice

#### 4.1.1   Procedures to Follow

There are several general philosophies that are helpful when designing or redesigning jobs or teams:

1. As noted previously, designs are not inalterable or dictated by technology. There is some discretion in the design of all work situations and considerable discretion in most.
2. There is no single best design; there are simply better and worse designs depending on one's design perspective.
3. Design is iterative and evolutionary and should continue to change and improve over time.
4. Participation of workers affected generally improves the quality of the resulting design and acceptance of suggested changes.
5. The process of the project, or how it is conducted, is important in terms of involvement of all interested parties, consideration of alternative motivations, and awareness of territorial boundaries.

***Procedures for the Initial Design of Jobs or Teams***   In consideration of process aspects of design, Davis and Wacker (1982) suggest four steps:

1. *Form a steering committee.* This committee usually consists of a team of high-level executives who have a direct stake in the new jobs or teams. The purposes of the committee are to (a) bring into focus the project's objective, (b) provide resources and support for the project, (c) help gain cooperation of all parties affected, and (d) oversee and guide the project.
2. *Form a design task force.* The task force may include engineers, managers, job or team design experts, architects, specialists, and others with relevant knowledge or responsibility. The task force is to gather data, generate and evaluate design alternatives, and help implement recommended designs.
3. *Develop a philosophy statement.* The first goal of the task force is to develop a philosophy statement to guide decisions involved in the project. The philosophy statement is developed with input from the steering committee and may include the project's purposes, organization's strategic goals, assumptions about workers and the nature of work, and process considerations.
4. *Proceed in an evolutionary manner.* Jobs should not be overspecified. With considerable input from eventual job holders or team members, the work design will continue to change and improve over time.

According to Davis and Wacker (1982), the process of redesigning existing jobs is much the same as designing original jobs with two additions. First, existing job incumbents must be involved. Second, more attention needs to be given to implementation issues. Those involved in the implementation must feel ownership of and commitment to the change and believe the redesign represents their own interests.

***Potential Steps to Follow***   Along with the steps discussed above, a redesign project should also include the following five steps:

1. *Measuring Design of Existing job or Teams.* The questionnaire methodology and other analysis tools described in Section 5 may be used to measure current jobs or teams.
2. *Diagnosing Potential Design Problems.* Based on data collected in step 1, the current design is analyzed for potential problems. The task force and employee involvement are important. Focused team meetings are a useful vehicle for identifying and evaluating problems.
3. *Determining Job or Team Design Changes.* Changes will be guided by project goals, problems identified in step 2, and one or more of the approaches to work design. Often several potential changes are generated and evaluated. Evaluation of alternative changes may involve consideration of advantages and disadvantages identified in previous research (see Table 1) and opinions of engineers, managers, and employees.
4. *Making Design Changes.* Implementation plans should be developed in detail along with back-up plans in case there are difficulties with the new design. Communication and training are keys to implementation. Changes might also be pilot tested before widespread implementation.
5. *Conducting Follow-Up Evaluation.* Evaluating the new design after implementation is probably the most neglected part of the process in most applications. The evaluation might include the collection of design measurements on the redesigned jobs/teams using the same instruments as in step 1. Evaluation may also be conducted on outcomes, such as employee satisfaction, error rates, and training time (Table 1). Scientifically valid evaluations require experimental research strategies with control groups. Such studies may not always be possible in organizations, but often quasi-experimental and other field research designs are possible (Cook and Campbell, 1979). Finally, the need for adjustments is identified through the follow-up evaluation. (For examples of evaluations, see Section 5.8 and Campion and McClelland, 1991, 1993.)

### 4.1.2 Individual Differences Among Workers

It is a common observation that not all employees respond the same to the same job. Some people on a job have high satisfaction, whereas others on the same job have low satisfaction. Clearly, there are individual differences in how people respond to work. Considerable research has looked at individual differences in reaction to the motivational design approach. It has been found that some people respond more positively than others to highly motivational work. These differences are generally viewed as differences in needs for personal growth and development (Hackman and Oldham, 1980).

Using the broader notion of preferences/tolerances for types of work, the consideration of individual differences has been expanded to all four approaches to job design (Campion, 1988; Campion and McClelland, 1991) and to the team design approach (Campion et al., 1993; Campion et al., 1996). Table 7 provides scales that can be used to determine job incumbents' preferences/tolerances. These scales can be administered in the same manner as the questionnaire measures of job and team design discussed in Section 5.

Although consideration of individual differences is encouraged, there are often limits to which such differences can be accommodated. Jobs or teams may have

---

**Table 7  Preferences/Tolerances for the Design Approaches**

*Instructions:* Indicate the extent to which each statement is descriptive of your preferences and tolerances for types of work on the scale below. Circle answers to the right of each statement.
*Please use the following scale*:

| | |
|---|---|
| **(5)** | Strongly agree |
| **(4)** | Agree |
| **(3)** | Neither agree nor disagree |
| **(2)** | Disagree |
| **(1)** | Strongly disagree |
| **( )** | Leave blank if do not know or not applicable |

*Preferences/Tolerances for Mechanistic Design*

| | | | | | | |
|---|---|---|---|---|---|---|
| 1. | I have a high tolerance for routine work. | 1 | 2 | 3 | 4 | 5 |
| 2. | I prefer to work on one task at a time. | 1 | 2 | 3 | 4 | 5 |
| 3. | I have a high tolerance for repetitive work. | 1 | 2 | 3 | 4 | 5 |
| 4. | I prefer work that is easy to learn. | 1 | 2 | 3 | 4 | 5 |

*Preferences/Tolerances for Motivational Design*

| | | | | | | |
|---|---|---|---|---|---|---|
| 5. | I prefer highly challenging work that taxes my skills and abilities. | 1 | 2 | 3 | 4 | 5 |
| 6. | I have a high tolerance for mentally demanding work. | 1 | 2 | 3 | 4 | 5 |
| 7. | I prefer work that gives a great amount of feedback as to how I am doing. | 1 | 2 | 3 | 4 | 5 |
| 8. | I prefer work that regularly requires the learning of new skills. | 1 | 2 | 3 | 4 | 5 |
| 9. | I prefer work that requires me to develop my own methods, procedures, goals, and schedules. | 1 | 2 | 3 | 4 | 5 |
| 10. | I prefer work that has a great amount of variety in duties and responsibilities. | 1 | 2 | 3 | 4 | 5 |

*Preferences/Tolerances for Perceptual/Motor Design*

| | | | | | | |
|---|---|---|---|---|---|---|
| 11. | I prefer work that is very fast paced and stimulating. | 1 | 2 | 3 | 4 | 5 |
| 12. | I have a high tolerance for stressful work. | 1 | 2 | 3 | 4 | 5 |
| 13. | I have a high tolerance for complicated work. | 1 | 2 | 3 | 4 | 5 |
| 14. | I have a high tolerance for work where there are frequently too many things to do at one time. | 1 | 2 | 3 | 4 | 5 |

*Preferences/Tolerances for Biological Design*

| | | | | | | |
|---|---|---|---|---|---|---|
| 15. | I have a high tolerance for physically demanding work. | 1 | 2 | 3 | 4 | 5 |
| 16. | I have a fairly high tolerance for hot, noisy, or dirty work. | 1 | 2 | 3 | 4 | 5 |
| 17. | I prefer work that gives me some physical exercise. | 1 | 2 | 3 | 4 | 5 |
| 18. | I prefer work that gives me some opportunities to use my muscles. | 1 | 2 | 3 | 4 | 5 |

*Preferences/Tolerances for Team Work*

| | | | | | | |
|---|---|---|---|---|---|---|
| 19. | If given the choice, I would prefer to work as part of a team rather than work alone. | 1 | 2 | 3 | 4 | 5 |
| 20. | I find that working as a member of a team increases my ability to perform effectively. | 1 | 2 | 3 | 4 | 5 |
| 21. | I generally prefer to work as part of a team. | 1 | 2 | 3 | 4 | 5 |

*Source*: Table adapted from Campion (1988) and Campion et al. (1993).
*Note*: See reference for reliability and validity information. Scores for each preference/tolerance are calculated by averaging applicable items. Interpretations differ slightly across the scales. For the mechanistic and motivational designs, higher scores suggest more favorable reactions from incumbents to well-designed jobs. For the perceptual/motor and biological approaches, higher scores suggest less unfavorable reactions from incumbents to poorly designed jobs.

to be designed for people who are not yet known or who differ in their preferences. Fortunately, although evidence indicates individual differences moderate reactions to the motivational approach (Fried and Ferris, 1987), the differences are of degree but not direction. That is, some people respond more positively than others to motivational work, but few respond negatively. It is likely that this also applies to the other design approaches.

### 4.1.3 Some Basic Choices

Hackman and Oldham (1980) have provided five strategic choices that relate to implementing job redesign. The note that little research exists indicating the exact consequences of each choice, and correct choices may differ by organization. The basic choices are:

1. *Individual versus Team Designs for Work*. An initial decision is to either enrich individual jobs or create teams. This also includes consideration of whether any redesign should be undertaken and its likelihood of success.
2. *Theory Based versus Intuitive Changes*. This choice was basically defined as the motivational (theory) approach versus no particular (atheoretical) approach. In the present chapter, this choice may be better framed as choosing among the four approaches to job design. However, as argued earlier, consideration of only one approach may lead to some costs or additional benefits being ignored.
3. *Tailored versus Broadside Installation*. This choice is between tailoring changes to individuals and making the changes for all in a given job.
4. *Participative versus Top-Down Change Processes*. The most common orientation is that participative is best. However, costs of participation include the time involved and incumbents' possible lack of a broad knowledge of the business.
5. *Consultation versus Collaboration with Stakeholders*. The effects of job design changes often extend far beyond the individual incumbent and department. For example, a job's output may be an input to a job elsewhere in the organization. The presence of a union also requires additional collaboration. Depending on considerations, participation of stakeholders may range from no involvement through consultation to full collaboration.

### 4.1.4 Overcoming Resistance to Change in Redesign Projects

Resistance to change can be a problem in any project involving major changes (Morgeson et al., 1997). Failure rates of new technology implementations demonstrate a need to give more attention to the human aspects of change projects. This concern has also been reflected in the area of participatory ergonomics, which encourages the use of participatory techniques when undertaking an ergonomic intervention (Wilson and Haines, 1997). It has been estimated that between 50 and 75% of

newly implemented manufacturing technologies in the United States have failed, with a disregard for human and organizational issues considered to be a bigger cause for the failures than technical problems (Majchrzak, 1988; Turnage, 1990). The number one obstacle to implementation was considered to be human resistance to change (Hyer, 1984).

Based on the work of Majchrzak (1988), Gallagher and Knight (1986), and Turnage (1990), guidelines for reducing resistance to change include the following:

1. *Involve workers in planning the change*. Workers should be informed of changes in advance and involved in the process of diagnosing current problems and developing solutions. Resistance is decreased if participants feel the project is their own and not imposed from outside and if the project is adopted by consensus.
2. *Top management should strongly support the change*. If workers feel management is not strongly committed, they are less likely to take the project seriously.
3. *Create change consistent with worker needs and existing values*. Resistance is less if change is seen to reduce present burdens, offer interesting experience, and not threaten worker autonomy or security or be inconsistent with other goals and values in the organization. Workers need to see the advantages to them of the change. Resistance is less if proponents of change can empathize with opponents (recognize valid objections and relieve unnecessary fears).
4. *Create an environment of open, supportive communication*. Resistance will be lessened if participants experience support and have trust in each other. Resistance can be reduced if misunderstandings and conflicts are expected as natural to the innovation process. Provision should be made for clarification.
5. *Allow for flexibility*. Resistance is reduced if the project is kept open to revision and reconsideration with experience.

## 4.2 Implementation Advice for Job Design and Redesign

### 4.2.1 Methods for Combining Tasks

In many cases, designing jobs is largely a function of combining tasks. Some guidance can be gained by extrapolating from specific design recommendations in Table 2. For example, variety in the motivational approach can be increased by simply combining different tasks in the same job. Conversely, specialization from the mechanistic approach can be increased by only including very similar tasks in the same job. It is also possible when designing jobs to first generate alternative task combinations, then evaluate them using the design approaches in Table 2.

A small amount of research within the motivational approach has focused explicitly on predicting relationships between combinations of tasks and the design of resulting jobs (Wong, 1989; Wong and Campion, 1991). This research suggests that a job's motivational quality
**Figure 2** Effects of task design, interdependence, and similarity on motivational job design.

is a function of three task-level variables, as illustrated in Figure 2.

1. *Task Design*. The higher the motivational quality of individual tasks, the higher the motivational quality of a job. Table 2 can be used to evaluate individual tasks; then motivational scores for individual tasks can be summed together. Summing is recommended rather than averaging because both the motivational quality of the tasks and the number of tasks are important in determining a job's motivational quality (Globerson and Crossman, 1976).

2. *Task Interdependence*. Interdependence among tasks has been shown to be positively related to motivational value up to some moderate point; beyond that point increasing interdependence has been shown to lead to lower motivational value. Thus, for motivational jobs, the total amount of interdependence among tasks should be kept at a moderate level. Both complete independence and excessively high interdependence should be avoided. Table 8 contains the dimension of task interdependence and provides a questionnaire to measure it. Table 8 can be used to judge the interdependence of each pair of tasks that are being evaluated for inclusion in a job.

3. *Task Similarity*. Similarity among tasks may be the oldest rule of job design, but beyond a moderate level, it tends to decrease a job's motivational value. Thus, to design motivational jobs, high levels of similarity should be avoided. Similarity at the task pair level can be judged in much the same manner as interdependence by using dimensions in Table 8 (see the note to Table 8).

### 4.2.2 Trade-Offs among Job Design Approaches

Although one should strive to construct jobs that are well designed on all the approaches, it is clear design approaches conflict. As Table 1 illustrates, benefits of some approaches are costs of others. No one approach satisfies all outcomes. The greatest potential conflicts are between the motivational and the mechanistic and perceptual/motor approaches. They produce nearly opposite outcomes. The mechanistic and perceptual/motor approaches recommend jobs that are simple, safe, and reliable, with minimal mental demands on workers. The motivational approach encourages more complicated and stimulating jobs, with greater mental demands. The team approach is consistent with the motivational approach and therefore also may conflict with the mechanistic and perceptual/motor approaches.

Because of these conflicts, trade-offs may be necessary. Major trade-offs will be in the mental demands created by the alternative design strategies. Making jobs more mentally demanding increases the likelihood of achieving workers' goals of satisfaction and motivation but decreases the chances of reaching the organization's goals of reduced training, staffing costs, and errors. Which trade-offs will be made depends on outcomes one prefers to maximize. Generally, a compromise may be optimal.

Trade-offs may not always be needed, however. Jobs can often be improved on one approach while still maintaining their quality on other approaches. For example, in one redesign study, the motivational approach was applied to clerical jobs to improve employee satisfaction and customer service (Campion and McClelland, 1991). Expected benefits occurred along with some expected costs (e.g., increased training and compensation requirements), but not all potential costs occurred (e.g., quality and efficiency did not decrease).

In another redesign study, Morgeson and Campion (2002) sought to increase both satisfaction and efficiency in jobs at a pharmaceutical company. They found that when jobs were designed to increase only satisfaction or only efficiency, the common trade-offs were present (e.g., increased or decreased satisfaction, training requirements). When jobs were designed to increase both satisfaction and efficiency, however, these trade-offs were reduced. They suggested that a work design process that explicitly considers both motivational and mechanistic aspects of work is key to avoiding the trade-offs.

Another strategy for minimizing trade-offs is to avoid design decisions that influence the mental demands of jobs. An example of this is to enhance motivational design by focusing on social aspects (e.g., communication, participation, recognition, feedback). These design features can be raised without incurring costs of increased mental demands. Moreover, many of these features are under the direct control of managers.

The independence of the biological approach provides another opportunity to improve design without incurring trade-offs with other approaches. One can reduce physical demands without affecting mental demands of a job. Of course, the cost of equipment may need to be considered.

Adverse effects of trade-offs can often be reduced by avoiding designs that are extremely high or low on any approach. Or, alternatively, one might require minimum acceptable levels on each approach. Knowing all approaches and their corresponding outcomes will

**Table 8 Dimensions of Task Interdependence**

*Instructions:* Indicate the extent to which each statement is descriptive of the pair of tasks using the scale below. Circle answers to the right of each statement. Scores are calcualted by averaging applicable items.
*Please use the following scale*:

| | |
|---|---|
| **(5)** | Strongly agree |
| **(4)** | Agree |
| **(3)** | Neither agree nor disagree |
| **(2)** | Disagree |
| **(1)** | Strongly disagree |
| **( )** | Leave blank if do not know or not applicable |

*Inputs of the Tasks*

1. Materials/supplies: One task obtains, stores, or prepares the materials or supplies necessary to perform the other task.  1 2 3 4 5
2. Information: One task obtains or generates information for the other task.  1 2 3 4 5
3. Product/service: One task stores, implements, or handles the products or services produced by the other task.  1 2 3 4 5

*Processes of the Tasks*

4. Input–output relationship: The products (or outputs) of one task are the supplies (or inputs) necessary to perform the other task.  1 2 3 4 5
5. Method and procedure: One task plans the procedures or work methods for the other task.  1 2 3 4 5
6. Scheduling: One task schedules the activities of the other task.  1 2 3 4 5
7. Supervision: One task reviews or checks the quality of products or services produced by the other task.  1 2 3 4 5
8. Sequencing: One task needs to be performed before the other task.  1 2 3 4 5
9. Time sharing: Some of the work activities of the two tasks must be performed at the same time.  1 2 3 4 5
10. Support service: The purpose of one task is to support or otherwise help the other task get performed.  1 2 3 4 5
11. Tools/equipment: One task produces or maintains the tools or equipment used by the other task.  1 2 3 4 5

*Outputs of the Tasks*

12. Goal: One task can only be accomplished when the other task is properly performed.  1 2 3 4 5
13. Performance: How well one task is performed has a great impact on how well the other task can be performed.  1 2 3 4 5
14. Quality: The quality of the product or service produced by one task depends on how well the other task is performed.  1 2 3 4 5

*Source*: Table adapted from Wong and Campion (1991). See reference and Wong (1989) for reliability and validity information.
*Note*: The task similarity measure contains 10 comparable items (excluding items 4, 6, 8, 9, and 14 and including an item on customer/client). Scores for each dimension are calculated by averaging applicable items.

help one make more informed decisions and avoid unanticipated consequences.

### 4.2.3 Other Implementation Advice for Job Design and Redesign

Griffin (1982) provides advice geared toward managers considering a job redesign intervention in their area. He notes that managers may also rely on consultants, task forces, or informal discussion groups. Griffin suggests nine steps:

1. Recognition of a need for change
2. Selection of job redesign as a potential intervention
3. Diagnosis of the work system and content on the following factors:
    a. Existing jobs
    b. Existing workforce
    c. Technology
    d. Organization design
    e. Leader behaviors
    f. Team and social processes
4. Cost/benefit analysis of proposed changes
5. Go/no-go decision
6. Establishment of a strategy for redesign
7. Implementation of the job changes
8. Implementation of any needed supplemental changes
9. Evaluation of the redesigned jobs

Recently, researchers have begun to study the manner in which employees are proactive actors in the job design process. Employees can either actively craft or change their jobs or they can negotiate idiosyncratic deals that alter the design of their work (Wrzesniewski and Dutton, 2001; Grant and Parker, 2009; Rousseau et al., 2006; Hornung et al., 2008). An idiosyncratic deal is a formal agreement that an employee and his or her manager or organization come to regarding the individual's work which creates a difference in the characteristics of the employee's work from the characteristics of the work of employees in a similar position. These types of deals represent formal individualized work design arrangements.

Job crafting differs from traditional job design as it describes the changes that employees make to their jobs. While traditional job design is implemented by a manager or an organization, job crafting refers to the informal changes to task or social characteristics that employees make to their work. The implications of these behaviors are that employees will informally change the design of their work. Being informal, they often go undetected and can be difficult for a manger to control. Managers should both recognize that these changes occur and design employees' work with the understanding that the design of the work can and probably will be altered to some degree by the employee.

## 4.3 Implementation Advice for Team Design

### 4.3.1 Deciding on Team Composition

Research encourages heterogeneous teams in terms of skills, personality, and attitudes because it increases the range of competencies in teams (Gladstein, 1984) and is related to effectiveness (Campion et al., 1996). However, homogeneity is preferred if team morale is the main criterion, and heterogeneous attributes must be complementary if they are to contribute to effectiveness. Heterogeneity for its own sake is unlikely to enhance effectiveness (Campion et al., 1993). Another composition characteristic of effective teams is whether members have flexible job assignments (Campion et al., 1993; Sundstrom et al., 1990). If members can perform different jobs, effectiveness is enhanced because they can fill in as needed.

A third important aspect of composition is team size. Evidence suggests the importance of optimally matching team size to team tasks to achieve high performance and satisfaction. Teams need to be large enough to accomplish work assigned to them but may be dysfunctional when too large due to heightened coordination needs (O'Reilly and Roberts, 1977; Steiner, 1972) or increased social loafing (McGrath, 1984; Wicker et al., 1976). Thus, groups should be staffed to the smallest number needed to do the work (Goodman et al., 1986; Hackman, 1987; Sundstrom et al., 1990).

### 4.3.2 Selecting Team Members

With team design, interpersonal demands appear to be much greater than with traditional individual-based job design (Lawler, 1986). A team-based setting highlights the importance of employees being capable of interacting in an effective manner with peers because the amount of interpersonal interactions required is higher in teams (Stevens and Campion, 1994a,b, 1999). Team effectiveness can depend heavily on members' "interpersonal competence" or their ability to successfully maintain healthy working relationships and react to others with respect for their viewpoints (Perkins and Abramis, 1990). There is a greater need for team members to be capable of effective interpersonal communication, collaborative problem solving, and conflict management (Stevens and Campion, 1994a,b, 1999).

The process of employment selection for team members places greater stress on adequately evaluating interpersonal competence than is normally required in the selection of workers for individual jobs. To create a selection instrument for evaluating potential team members' ability to work successfully in teams, Stevens and Campion (1994a,b) reviewed literature in areas of sociotechnical systems theory (e.g., Cummings, 1978; Wall et al., 1986), organizational behavior (e.g., Hackman, 1987; Shea and Guzzo, 1987; Sundstrom et al., 1990), industrial engineering (e.g., Davis and Wacker, 1987; Majchrzak, 1988), and social psychology (e.g., McGrath, 1984; Steiner, 1972) to identify relevant KSAs. Table 9 shows the 14 KSAs identified as important for teamwork.

These KSAs have been used to develop a 35-item, multiple-choice employment test which was validated in two studies to determine how highly related it was to team members' job performance (Stevens and Campion, 1999). The job performance of team members in two different companies was rated by both supervisors and co-workers. Correlations between the test and job performance ratings were significantly high, with some correlations exceeding 0.50. The test was also able to add to the ability to predict job performance beyond that provided by a large battery of traditional employment aptitude tests. Thus, these findings provide support for the value of the teamwork KSAs and a selection test based on them (Stevens and Campion, 1994a). Table 10 shows some example items from the test.

Aside from written tests, there may be other ways teamwork KSAs could be measured for purposes of selection. For example, interviews may be especially suited to measuring interpersonal attributes (e.g., Posthuma et al., 2002). There is evidence that a structured interview specifically designed to measure social (i.e., nontechnical) KSAs can have validity with job performance and predict incrementally beyond traditional employment tests (Campion et al., 1994a).

Assessment center techniques might also lend themselves to measuring teamwork KSAs. Group exercises have been used to measure leadership and other social skills with good success (Gaugler et al., 1987). It is likely that existing team exercises, such as group problem-solving tasks, could also be modified to score teamwork KSAs.

Selection techniques using biodata may be another way to measure teamwork KSAs. Many items in biodata instruments reflect previous life experiences of a social nature, and recruiters interpret biodata information on applications and resumes as reflecting attributes such as interpersonal skills (Brown and Campion, 1994).

**Table 9  Knowledge, Skill, and Ability (KSA) Requirements for Teamwork**

I.   Interpersonal KSAs
 A.   Conflict Resolution KSAs
  1.   The KSA to recognize and encourage desirable but discourage undesirable team conflict.
  2.   The KSA to recognize the type and source of conflict confronting the team and to implement an appropriate conflict resolution strategy.
  3.   The KSA to employ an integrative (win–win) negotiation strategy rather than the traditional distributive (win–lose) strategy.
 B.   Collaborative Problem-Solving KSAs
  4.   The KSA to identify situations requiring participative group problem solving and to utilize the proper degree and type of participation.
  5.   The KSA to recognize the obstacles to collaborative group problem solving and implement appropriate corrective actions.
 C.   Communication KSAs
  6.   The KSA to understand communication networks and to utilize decentralized networks to enhance communication where possible.
  7.   The KSA to communicate openly and supportively, that is, to send messages which are (a) behavior or event oriented, (b) congruent, (c) validating, (d) conjunctive, and (e) owned.
  8.   The KSA to listen nonevaluatively and to appropriately use active listing techniques.
  9.   The KSA to maximize consonance between nonverbal and verbal messages and to recognize and interpret the nonverbal messages of others.
  10.  The KSA to engage in ritual greetings and small talk and a recognition of their importance.
II.  Self-Management KSAs
 D.   Goal Setting and Performance Management KSAs
  11.  The KSA to help establish specific, challenging, and accepted team goals.
  12.  The KSA to monitor, evaluate, and provide feedback on both overall team performance and individual team member performance.
 E.   Planning and Task Coordination KSAs
  13.  The KSA to coordinate and synchronize activities, information, and task interdependencies between team members.
  14.  The KSA to help establish task and role expectations of individual team members and to ensure proper balancing of workload in the team.

**Table 10  Example Items from the Teamwork KSA Test**

1.  Suppose you find yourself in an argument with several co workers who should do a very disagreeable but routine task. Which of the following would likely be the most effective way to resolve this situation?
 A.   Have your supervisor decide, because this would avoid any personal bias.
 *B.  Arrange for a rotating schedule so everyone shares the chore.
 C.   Let the workers who show up earliest choose on a first come, first served basis.
 D.   Randomly assign a person to do the task and don't change it.
2.  Your team wants to improve the quality and flow of the conversations among its members. Your team should:
 *A.  Use comments that build upon and connect to what others have said.
 B.   Set up a specific order for everyone to speak and then follow it.
 C.   Let team members with more to say determine the direction and topic of conversation.
 D.   Do all of the above.
3.  Suppose you are presented with the following types of goals. You are asked to pick one for your team to work on. Which would you choose?
 A.   An easy goal to ensure the team reaches it, thus creating a feeling of success.
 B.   A goal of average difficulty so the team will be somewhat challenged but successful without too much effort.
 *C.  A difficult and challenging goal that will stretch the team to perform at a high level but one that is attainable so that effort will not be seen as futile.
 D.   A very difficult or even impossible goal so that even if the team falls short, it will at least have a very high target to aim for.

*Note*: asterisk indicates correct answer.

A biodata measure developed to focus on teamwork KSAs might include items on teamwork in previous jobs, team experiences in school (e.g., college clubs, class projects), and recreational activities of a team nature (e.g., sports teams and social groups).

### 4.3.3  Designing the Teams' Jobs

This aspect of team design involves team characteristics derived from the motivational job design approach. The main distinction is in level of application rather than content (Campion and Medsker, 1992; Shea and Guzzo, 1987; Wall et al., 1986). All the job characteristics of the motivational approach to job design can be applied to team design.

One such characteristic is self-management, which is the team-level analogy to autonomy at the individual job level. It is central to many definitions of effective work

teams (e.g., Cummings, 1978, 1981; Hackman, 1987). A related characteristic is participation. Regardless of management involvement in decision making, teams can still be distinguished in terms of the degree to which all members are allowed to participate in decisions (McGrath, 1984, Porter et al., 1987). Self-management and participation are presumed to enhance effectiveness by increasing members' sense of responsibility and ownership of the work. These characteristics may also enhance decision quality by increasing relevant information and by putting decisions as near as possible to the point of operational problems and uncertainties.

Other important characteristics are task variety, task significance, and task identity. Variety motivates by allowing members to use different skills (Hackman, 1987) and by allowing both interesting and dull tasks to be shared among members (Davis and Wacker, 1987). Task significance refers to the perceived significance of the consequences of the team's work, for either others inside the organization or its customers. Task identity (Hackman, 1987), or task differentiation (Cummings, 1978), refers to the degree to which the team completes a whole and meaningful piece of work. These suggested characteristics of team design have been found to be positively related to team productivity, team member satisfaction, and managers' and employees' judgments of their teams' performance (Campion et al., 1993, 1995).

### 4.3.4 Developing Interdependent Relations

Interdependence is often the reason teams are formed (Mintzberg, 1979) and is a defining characteristic of teams (Salas et al., 1992; Wall et al., 1986). Interdependence has been found to be related to team members' satisfaction and team productivity and effectiveness (Campion et al., 1993, 1995).

One form of interdependence is task interdependence. Team members interact and depend on one another to accomplish their work. Interdependence varies across teams, depending on whether the work flow in a team is pooled, sequential, or reciprocal (Thompson, 1967). Interdependence among tasks in the same job (Wong and Campion, 1991) or between jobs (Kiggundu, 1983) has been related to increased motivation. It can also increase team effectiveness because it enhances the sense of responsibility for others' work (Kiggundu, 1983) or because it enhances the reward value of a team's accomplishments (Shea and Guzzo, 1987).

Another form of interdependence is goal interdependence. Goal setting is a well-documented, individual-level performance improvement technique (Locke and Latham, 1990). A clearly defined mission or purpose is considered to be critical to team effectiveness (Campion et al., 1993, 1995; Davis and Wacker, 1987; Hackman, 1987; Sundstrom et al., 1990). Its importance has also been shown in empirical studies on teams (e.g., Buller and Bell, 1986; Woodman and Sherwood, 1980). Not only should goals exist for teams, but individual members' goals must be linked to team goals to be maximally effective.

Finally, interdependent feedback and rewards have also been found to be important for team effectiveness and team member satisfaction (Campion et al., 1993, 1995). Individual feedback and rewards should be linked to a team's performance in order to motivate team-oriented behavior. This characteristic is recognized in many theoretical treatments (e.g., Hackman, 1987; Leventhal, 1976; Steiner, 1972; Sundstrom et al., 1990) and research studies (e.g., Pasmore et al., 1982; Wall et al., 1986).

### 4.3.5 Creating the Organizational Context

Organizational context and resources are considered in all recent models of work team effectiveness (e.g., Guzzo and Shea, 1992; Hackman, 1987). One important aspect of context and resources for teams is adequate training. Training is an extensively researched determinant of team performance (for reviews see Dyer, 1984; Salas et al., 1992), and training is included in most interventions (e.g., Pasmore et al., 1982; Wall et al., 1986). Training is related to team members' satisfaction and managers' and employees' judgments of their teams' effectiveness (Campion et al., 1993, 1995).

Training content often includes team philosophy, group decision making, and interpersonal skills as well as technical knowledge. Many team-building interventions focus on aspects of team functioning that are related to the teamwork KSAs shown in Table 9. A recent review of this literature divided such interventions into four approaches (Tannenbaum et al., 1992)—goal setting, interpersonal, role, and problem solving—which are similar to the teamwork KSA categories. Thus, these interventions could be viewed as training programs on teamwork KSAs. Reviews indicate that the evidence for the effectiveness of this training appears positive despite the methodological limitations that plague this research (Buller and Bell, 1986; Tannenbaum et al., 1992; Woodman and Sherwood, 1980). It appears that workers can be trained in teamwork KSAs. (See Chapter 16 for more information on team training.)

Regarding how such training should be conducted, there is substantial guidance on training teams in the human factors and military literatures (Dyer, 1984; Salas et al., 1992; Swezey and Salas, 1992). Because these topics are thoroughly addressed in the cited sources, they will not be reviewed here.

Managers of teams also need to be trained in teamwork KSAs, regardless of whether the teams are manager led or self-managed. The KSAs are needed for interacting with employee teams and for participating on management teams. It has been noted that managers of teams, especially autonomous work teams, need to develop their employees (Cummings, 1978; Hackman and Oldham, 1980; Manz and Sims, 1987). Thus, training must ensure not only that managers possess teamwork KSAs but also that they know how to train employees on these KSAs.

Managerial support is another contextual characteristic (Morgeson, 2005). Management controls resources (e.g., material and information) required to make team functioning possible (Shea and Guzzo, 1987), and an organization's culture and top management must support

the use of teams (Sundstrom et al., 1992). Teaching facilitative leadership to managers is often a feature of team interventions (Pasmore et al., 1982). Finally, communication and cooperation between teams are contextual characteristics because they are often the responsibility of managers. Supervising team boundaries (Cummings, 1978) and externally integrating teams with the rest of the organization (Sundstrom et al., 1990) enhance effectiveness. Research indicates that managerial support and communication and cooperation between work teams are related to team productivity and effectiveness and to team members' satisfaction with their work (Campion et al., 1993, 1995).

### 4.3.6  Developing Effective Team Process

Process describes those things that go on in the group that influence effectiveness. One process characteristic is potency, or the belief of a team that it can be effective (Guzzo and Shea, 1992; Shea and Guzzo, 1987). It is similar to the lay-term "team spirit." Hackman (1987) argues that groups with high potency are more committed and willing to work hard for the group, and evidence indicates that potency is highly related to team members' satisfaction with work, team productivity, and members' and managers' judgments of their teams' effectiveness (Campion et al., 1993, 1995).

Another process characteristic found to be related to team satisfaction, productivity, and effectiveness is social support (Campion et al., 1993, 1995). Effectiveness can be enhanced when members help each other and have positive social interactions. Like social facilitation (Harkins, 1987; Zajonc, 1965), social support can be arousing and may enhance effectiveness by sustaining effort on mundane tasks.

Another process characteristic related to satisfaction, productivity, and effectiveness is workload sharing (Campion et al.1993, 1995). Workload sharing enhances effectiveness by preventing social loafing or free riding (Harkins, 1987). To enhance sharing, group members should believe their individual performance can be distinguished from the group's and that there is a link between their performance and outcomes.

Finally, communication and cooperation within the work group are also important to team effectiveness, productivity, and satisfaction (Campion et al. 1993, 1995). Management should help teams foster open communication, supportiveness, and discussions of strategy. Informal, rather than formal, communication channels and mechanisms of control should be promoted to ease coordination (Bass and Klubeck, 1952; Majchrzak, 1988). Managers should encourage self-evaluation, self-observation, self-reinforcement, self-management, and self-goal setting by teams. Self-criticism for purposes of recrimination should be discouraged (Manz and Sims, 1987).

Recent meta-analytic evidence suggests that numerous team processes are related to both team performance and member satisfaction (LePine et al., 2008). Many of these processes can be grouped into three categories. Transition processes are team actions that occur after one team task has ended and before the next begins and include actions such as mission analysis, goal specification, and strategy formulation/planning. Action processes are team activities that occur during the completion of a task. The four types of action processes include monitoring progress toward goals, systems monitoring (assessing resources and environmental factors that could influence goal accomplishment), team monitoring and backup behavior (team members assisting each other in their individual tasks), and coordination. Finally, team activities geared toward maintaining the team's interpersonal relationships are called interpersonal processes and include conflict management, motivating/confidence building, and affect management (e.g., emotional balance, togetherness, and coping with demands/frustrations). The results suggest that there are specific team processes that occur at different stages of task completion, and the occurrence, or lack thereof, of these processes has an impact on both the teams' performance and team members' satisfaction (LePine et al. 2008).

## 5  MEASUREMENT AND EVALUATION OF JOB AND TEAM DESIGN

The purpose of an evaluation study for either a job or team design is to provide an objective evaluation of success and to create a tracking and feedback system to make adjustments during the course of the design project. An evaluation study can provide objective data to make informed decisions, help tailor the process to the organization, and give those affected by the design or redesign an opportunity to provide input (see Morgeson and Campion, 2002). An evaluation study should include measures that describe the characteristics of the jobs or teams so that it can be determined whether or not jobs or teams ended up having the characteristics they were intended to have. An evaluation study should also include measures of effectiveness outcomes an organization hoped to achieve with a design project. Measures of effectiveness could include such *subjective* outcomes as employee job satisfaction or employee, manager, or customer perceptions of effectiveness. Measures of effectiveness should also include *objective* outcomes such as cost, productivity, rework/scrap, turnover, accident rates, or absenteeism. Additional information on measurement and evaluation of such outcomes can be found in Part 6 of this handbook.

### 5.1  Using Questionnaires to Measure Job and Team Design

One way to measure job or team design is by using questionnaires or checklists. This method of measuring job or team design is highlighted because it has been used widely in research on job design, especially on the motivational approach. More importantly, questionnaires are a very inexpensive, easy, and flexible way to measure work design characteristics. Moreover, they gather information from job experts, such as incumbents, supervisors, and engineers and other analysts.

Several questionnaires exist for measuring the motivational approach to job design (Hackman and Oldham, 1980; Sims et al., 1976), but only one questionnaire, the

*multimethod job design questionnaire*, measures characteristics for all four approaches to job design. This questionnaire (presented in Table 2) evaluates the quality of a job's characteristics based on each of the four approaches. The *team design measure* (presented in Table 4) evaluates the quality of work design based on the team approach.

Questionnaires can be administered in a variety of ways. Employees can complete them individually at their convenience at their work station or some other designated area or they can complete them in a group setting. Group administration allows greater standardization of instructions and provides the opportunity to answer questions and clarify ambiguities. Managers and engineers can also complete the questionnaires either individually or in a group session. Engineers and analysts usually find that observation of the work site, examination of the equipment and procedures, and discussions with any incumbents or managers are important methods of gaining information on the work before completing the questionnaires.

Scoring for each job design approach or for each team characteristic on the questionnaires is usually accomplished by simply averaging the applicable items. Then scores from different incumbents, managers, or engineers describing the same job or team are combined by averaging. Multiple items and multiple respondents are used to improve the reliability and accuracy of the results. The implicit assumption is that slight differences among respondents are to be expected because of legitimate differences in viewpoint. However, absolute differences in scores should be examined on an item-by-item basis, and large discrepancies (e.g., more than one point) should be discussed to clarify possible differences in interpretation. It may be useful to discuss each item until a consensus rating is reached.

The higher the score on a particular job design scale or work team characteristic scale, the better the quality of the design in terms of that approach or characteristic. Likewise, the higher the score on a particular item, the better the design is on that dimension. How high a score is needed or necessary cannot be stated in isolation. Some jobs or teams are naturally higher or lower on the various approaches, and there may be limits to the potential of some jobs. The scores have most value in comparing different jobs, teams, or design approaches, rather than evaluating the absolute level of the quality of a job or team design. However, a simple rule of thumb is that if the score for an approach is smaller than 3, the job or team is poorly designed on that approach and it should be reconsidered. Even if the average score on an approach is greater than 3, examine any individual dimension scores that are at 2 or 1.

**Uses of Questionnaires in Different Contexts**:

1. *Designing New Jobs or Teams*. When jobs or teams do not yet exist, the questionnaire is used to evaluate proposed job or team descriptions, work stations, equipment, and so on. In this role, it often serves as a simple design checklist. Additional administrations of the questionnaire in later months or years can be used to assess the longer term effects of the job or team design.

2. *Redesigning Existing Jobs or Teams or Switching from Job to Team Design*. When jobs or teams already exist, there is a much greater wealth of information. Questionnaires can be completed by incumbents, managers, and engineers. Questionnaires can be used to measure design both before and after changes are made to compare the redesign with the previous design approach. A premeasure before the redesign can be used as a baseline measurement against which to compare a postmeasure conducted right after the redesign implementation. A follow-up measure can be used in later months or years to assess the long-term difference between the previous design approach and the new approach. If other sites or plants with the same types of jobs or teams are not immediately included in the redesign but are maintained with the older design approach, they can be used as a comparison or "control group" to enable analysts to draw even stronger conclusions about the effectiveness of the redesign. Such a control group allows one to control for the possibilities that changes in effectiveness were not due to the redesign but were in fact due to some other causes such as increases in workers' knowledge and skills with the passage of time, changes in workers' economic environment (i.e., job security, wages, etc.), or workers trying to give socially desirable responses to questionnaire items.

3. *Diagnosing Problem Job or Team Designs*. *When* problems occur, regardless of the apparent source of the problem, the job or team design questionnaires can be used as a diagnostic device to determine if any problems exist with the design of the jobs or teams.

## 5.2  Choosing Sources of Data

1. *Incumbents*. Incumbents are probably the best source of information for existing jobs or teams. Having input can enhance the likelihood that changes will be accepted, and involvement in such decisions can enhance feelings of participation, thus increasing motivational job design in itself (see item 22 of the motivational scale in Table 2). One should include a large number of incumbents for each job or team because there can be slight differences in perceptions of the same job or team due to individual differences (discussed in Section 4.1). Evidence suggests that one should include at least five incumbents for each job or team, but more are preferable (Campion, 1988; Campion and McClelland, 1991; Campion et al., 1993, 1995).

2. *Managers or Supervisors*. First-level managers or supervisors may be the next most knowledgeable persons about an existing work design. They may also provide information on jobs or teams under development. Some differences in perceptions of the same job or team will exist

among managers, so multiple managers should be used.

3. *Engineers or Analysts*. Engineers may be the only source of information if the jobs or teams are not yet developed. But also for existing jobs or teams, an outside perspective of an engineer, analyst, or consultant may provide a more objective viewpoint. Again, there can be differences among engineers, so several should evaluate each job or team.

It is desirable to get multiple inputs and perspectives from different sources in order to get the most reliable and accurate picture of the results of the job or team design.

## 5.3 Long-Term Effects and Potential Biases

It is important to recognize that some effects of job or team design may not be immediate, others may not be long lasting, and still others may not be obvious. Initially, when jobs or teams are designed, or right after they are redesigned, there may be a short-term period of positive attitudes (often called a "honeymoon effect"). As the legendary Hawthorne studies indicated, changes in jobs or increased attention paid to workers tends to create novel stimulation and positive attitudes (Mayo, 1933). Such transitory elevations in affect should not be mistaken for long-term improvements in satisfaction, as they may wear off over time. In fact, with time, employees may realize their work is now more complex and should be paid higher compensation (Campion and Berger, 1990).

Costs which are likely to lag in time also include stress and fatigue, which may take a while to build up if mental demands have been increased excessively. Boredom may take a while to set in if mental demands have been overly decreased. In terms of lagged benefits, productivity and quality are likely to improve with practice and learning on the new job or team. And some benefits, like reduced turnover, simply take time to estimate accurately.

Benefits which may potentially dissipate with time include satisfaction, especially if the elevated satisfaction is a function of novelty rather than basic changes to the motivating value of the work. Short-term increases in productivity due to heightened effort rather than better design may not last. Costs which may dissipate include training requirements and staffing difficulties. Once jobs are staffed and everyone is trained, these costs disappear until turnover occurs. So these costs will not go away completely, but they may be less after initial start-up. Dissipating heightened satisfaction but long-term increases in productivity were observed in a motivational job redesign study conducted by Griffin (1991). These are only examples to illustrate how dissipating and lagged effects might occur. A more detailed example of long-term effects is given in Section 5.8.

A potential bias which may confuse the proper evaluation of benefits and costs is spillover. Laboratory research has shown that the job satisfaction of employees can bias perceptions of the motivational value of their jobs (O'Reilly et al., 1980). Likewise, the level of morale in the organization can have a spillover effect onto employees' perceptions of job or team design. If morale is particularly high, it may have an elevating effect on how employees or analysts view the jobs or teams; conversely, low morale may have a depressing effect on views. The term *morale* refers to the general level of job satisfaction across employees, and it may be a function of many factors, including management, working conditions, and wages. Another factor which has an especially strong effect on employee reactions to work design changes is *employment security*. Obviously, employee enthusiasm for work design changes will be negative if they view them as potentially decreasing their job security. Every effort should be made to eliminate these fears. The best method of addressing these effects is to be attentive to their potential existence and to conduct longitudinal evaluations of job and team design.

In addition to questionnaires, many other analytical tools are useful for work design. The disciplines that contributed the different approaches to work design have also contributed different techniques for analyzing tasks, jobs, and processes for design and redesign purposes. These techniques include job analysis methods created by specialists in industrial psychology, variance analysis methods created by specialists in sociotechnical design, time-and-motion analysis methods created by specialists in industrial engineering, and linkage analysis methods created by specialists in human factors. This section briefly describes a few of these techniques to illustrate the range of options. The reader is referred to the citations for detail on how to use the techniques.

## 5.4 Job Analysis

Job analysis can be broadly defined as a number of systematic techniques for collecting and making judgments about job information (Morgeson and Campion, 1997, 2000). Information derived from job analysis can be used to aid in recruitment and selection decisions, determine training and development needs, develop performance appraisal systems, and evaluate jobs for compensation as well as analyze tasks and jobs for job design. Job analysis may also focus on tasks, worker characteristics, worker functions, work fields, working conditions, tools and methods, products and services, and so on. Job analysis data can come from job incumbents, supervisors, and analysts who specialize in the analysis of jobs. Data may also be provided by higher management levels or subordinates in some cases.

Considerable literature has been published on the topic of job analysis (Ash et al., 1983; Dierdorff and Wilson, 2003; Gael, 1983; Harvey, 1991; Morgeson and Campion, 1997; Morgeson et al., 2004; Peterson et al., 2001; U.S. Department of Labor, 1972). Some of the more typical methods of analysis are briefly described below:

1. *Conferences and Interviews*. Conferences or interviews with job experts, such as incumbents and supervisors, are often the first step. During such meetings, information collected typically includes job duties and tasks, KSAs, and other worker characteristics.

2. *Questionnaires*. Questionnaires are used to collect information efficiently from a large number of people. Questionnaires require considerable prior knowledge of the job to form the basis of the items (e.g., primary tasks). Often this information is first collected through conferences and interviews, and then the questionnaire is constructed and used to collect judgments about the job (e.g., importance and time spent on each task). Some standardized questionnaires have been developed which can be applied to all jobs to collect basic information on tasks and requirements. Examples of standardized questionnaires are the position analysis questionnaire (McCormick et al., 1972) and the Occupational Information Network (O*NET; Peterson et al., 2001).

3. *Inventories*. Inventories are much like questionnaires, except they are simpler in format. They are usually simple checklists where the job expert checks whether a task is performed or an attribute is required.

4. *Critical Incidents*. This form of job analysis focuses only on aspects of worker behavior which are especially effective or ineffective.

5. *Work Observation and Activity Sampling*. Quite often job analysis includes the actual observation of work performed. More sophisticated technologies involve statistical sampling of work activities.

6. *Diaries*. Sometimes it is useful or necessary to collect data by having the employee keep a diary of activities on his or her job.

7. *Functional Job Analysis*. Task statements can be written in a standardized fashion. Functional job analysis suggests how to write task statements (e.g., start with a verb, be as simple and discrete as possible). It also involves rating jobs on the degree of data, people, and things requirements. This form of job analysis was developed by the U.S. Department of Labor and has been used to describe over 12,000 jobs as documented in the *Dictionary of Occupational Titles* (Fine and Wiley, 1971; U.S. Department of Labor, 1977).

Very limited research has been done to evaluate the practicality and quality of various job analysis methods for different purposes. But analysts seem to agree that combinations of methods are preferable to single methods (Levine et al., 1983; Morgeson and Campion, 1997).

Current approaches to job analysis do not give much attention to analyzing teams. For example, the *Dictionary of Occupational Titles* (U.S. Department of Labor, 1972) considers "people" requirements of jobs but does not address specific teamwork KSAs. Likewise, recent reviews of the literature mention some components of teamwork such as communication and coordination (e.g., Harvey, 1991) but give little attention to other teamwork KSAs. Thus, job analysis systems may need to be revised. The recent O*NET reflects a major new job analysis system designed to replace the *Dictionary of Titles* (Peterson et al., 2001). Although not explicitly addressing the issue of teamwork KSAs, it does contain a large number of worker attribute domains that may prove useful. Teamwork KSAs are more likely to emerge with conventional approaches to job analysis because of their unstructured nature (e.g., interviews), but structured approaches (e.g., questionnaires) will have to be modified to query about teamwork KSAs.

## 5.5 Other Approaches

Variance analysis is a tool used to identify areas of technological uncertainty in a production process (Davis and Wacker, 1982). It aids the organization in designing jobs to allow job holders to control the variability in their work. See Chapters 12 and 13 in this handbook for more information on task and workload analysis.

Industrial engineers have also created many techniques to help job designers visualize operations in order to improve efficiencies, which has led to the development of a considerable literature on the topic of time-and-motion analysis (e.g., Mundel, 1985; Niebel, 1988). Some of these techniques are *process charts* (graphically represent separate steps or events that occur during performance of a task or series of actions); *flow diagrams* (utilize drawings of an area or building in which an activity takes place and use lines, symbols, and notations to help designers visualize the physical layout of the work); *possibility guides* (tools for systematically listing all possible changes suggested for a particular activity or output, and examine the consequences of suggestions to aid in selecting the most feasible changes); and *network diagrams* (describe complex relationships, where a circle or square represents a "status," a partial or complete service, or substantive output; heavy lines represent "critical paths," which determine the minimum expected completion time for a project).

Linkage analysis is another technique used by human factors specialists to represent relationships (i.e., "links") between components (i.e., people or things) in a work system (Sanders and McCormick, 1987). Designers of physical work arrangements use tools (i.e., link tables, adjacency layout diagrams, and spatial operational sequences) to represent relationships between components in order to better understand how to arrange components to minimize the distance between frequent or important links.

## 5.6 Example of an Evaluation of a Job Design

Studies conducted by Campion and McClelland (1991, 1993) are described as an illustration of an evaluation of a job redesign project. They illustrate the value of considering an interdisciplinary perspective. The setting was a large financial services company. The units under study processed the paperwork in support of other units that sold the company's products. Jobs had been designed in a mechanistic manner such that individual employees prepared, sorted, coded, and computer input the paper flow.

The organization viewed the jobs as too mechanistically designed. Guided by the motivational approach, the project intended to enlarge jobs by combining existing

jobs in order to attain three objectives: (1) enhance motivation and satisfaction of employees, (2) increase incumbent feelings of ownership of the work, thus increasing customer service, and (3) maintain productivity in spite of potential lost efficiencies from the motivational approach. The consequences of all approaches to job design were considered. It was anticipated that the project would increase motivational consequences, decrease mechanistic and perceptual/motor consequences, and have no effect on biological consequences (Table 1).

The evaluation consisted of collecting detailed data on job design and a broad spectrum of potential benefits and costs of enlarged jobs. The research strategy involved comparing several varieties of enlarged jobs with each other and with unenlarged jobs. Questionnaire data were collected and focused team meetings were conducted with incumbents, managers, and analysts. The study was repeated at five different geographic sites.

Results indicated enlarged jobs had the benefits of more employee satisfaction, less boredom, better quality, and better customer service, but they also had the costs of slightly higher training, skill, and compensation requirements. Another finding was that all potential costs of enlarging jobs were not observed, suggesting that redesign can lead to benefits without incurring every cost in a one-to-one fashion.

In a two-year follow-up evaluation study, it was found that the costs and benefits of job enlargement changed substantially over time, depending on the type of enlargement. Task enlargement, which was the focus of the original study, had mostly long-term costs (e.g., lower satisfaction, efficiency, and customer service and more mental overload and errors). Conversely, knowledge enlargement, which emerged as a form of job design since the original study, had mostly benefits (e.g., higher satisfaction and customer service and lower overload and errors).

There are several important implications of the latter study. First, it illustrates that the long-term effects of job design changes can be different than the short-term effects. Second, it shows the classic distinction between enlargement and enrichment (Herzberg, 1966) in that simply adding more tasks did not improve the job, but adding more knowledge opportunities did. Third, it illustrates how the job design process is iterative. In this setting, the more favorable knowledge enlargement was discovered only after gaining experience with task enlargement. Fourth, as in the previous study, it shows that it is possible in some situations to gain benefits of job design without incurring all the potential costs, thus minimizing the trade-offs between the motivational and mechanistic approaches to job design.

## 5.7 Example of an Evaluation of a Team Design

Studies conducted by the authors and their colleagues are described here as an illustration of an evaluation of a team design project (Campion et al., 1993, 1995). They illustrate the use of multiple sources of data and multiple types of team effectiveness outcomes. The setting was the same financial services company as in the example job design evaluation above. Questionnaires based on Table 4 were administered to 391 clerical employees in 80 teams and 70 team managers in the first study (Campion et al., 1993) and to 357 professional workers in 60 teams (e.g., systems analysts, claims specialists, underwriters) and 93 managers in the second study (Campion et al., 1996) to measure teams' design characteristics. Thus, two sources of data were used, team members and team managers, to measure the team design characteristics.

In both studies, effectiveness outcomes included the organization's employee satisfaction survey, which had been administered at a different time than the team design characteristics questionnaire, and managers' judgments of teams' effectiveness, measured at the same time as the team design characteristics. In the first study, several months of records of team productivity were also used to measure effectiveness. Additional effectiveness measures in the second study were employees' judgments of their team's effectiveness, measured at the same time as the team design characteristics, managers' judgments of teams' effectiveness, measured a second time three months after the team design characteristics, and the average of team members' most recent performance ratings.

Results indicated that all of the team design characteristics had positive relationships with at least some of the outcomes. Relationships were strongest for process characteristics, followed by job design, context, interdependence, and composition characteristics (see Figure 1). Results also indicated that when teams were well designed according to the team design approach, they were higher on both employee satisfaction and team effectiveness ratings than less well designed teams.

Results were stronger when the team design characteristics data were from team members, rather than from the team managers. This illustrates the importance of collecting data from different sources to gain different perspectives on the results of a team design project. Collecting data from only a single source may lead one to draw different conclusions about a design project than if one obtains a broader picture of the team design results from multiple sources.

Results were also stronger when outcome measures came from employees (employee satisfaction, team member judgments of their teams), managers rating their own teams, or productivity records, than when they came from other managers or from performance appraisal ratings. This illustrates the use of different types of outcome measures to avoid drawing conclusions from overly limited data. This example also illustrates the use of separate data collection methods and times for collecting team design characteristics data versus team outcomes data. A single data collection method and time in which team design characteristics and outcomes are collected from the same source (e.g., team members only) on the same day can create an illusion of higher relationships between design characteristics and outcomes than really exist. Although it is more costly to use multiple sources, methods, and administration times, the ability to draw conclusions from the results is far stronger if one does.

## 1 INTRODUCTION

Major changes have taken place in the workplace over the last several decades and continue today. The globalization of numerous companies and industries, organizational downsizing and restructuring, expansion of information technology use at work, changes in work contracts, and increased use of alternative work strategies and schedules have transformed the nature of work in many organizations.

Technology alone changes the nature of work, and as Czaja (2001) has suggested, it will have a major impact on the future structure of the labor force, transforming the jobs that are available and how they are performed. Given the spreading use of technology in most occupations, it will likely create new jobs and opportunities for employment for some and eliminate jobs and create conditions of unemployment for other workers. It will also change the ways in which jobs are performed and alter job content and job demands.

The workforce itself is also changing, with a growing number of older workers, females, and dual-career couples. This means that organizations will need to

tailor their workplace policies to reflect a more diverse workforce.

More recently, economic conditions have also influenced how organizations approach attracting, hiring, and retaining employees. For example, in the United States alone, from January 2007 through December 2009, 6.9 million workers have been displaced from jobs they had held for at least three years (U.S. Department of Labor, 2010). Similar data from the Job Openings and Labor Turnover Survey, collected by the U. S Department of Labor, reflect the impact that a recession can have on the demand for labor and worker flows. Job openings (a measure of labor demand) and hires and separations (measures of worker flows) all declined during the 2007–2009 period and reached new lows in 2009 (deWolf and Klemmer, 2010).

These workforce changes are likely to result in different occupational and organizational structures in the future. A National Academy of Sciences report released in 2000 suggested that the nature of work is changing in ways that tend to blur the traditional distinctions between blue-collar and white-collar jobs (Committee

on Techniques for the Enhancement of Human Performance, 2000). For example, this committee suggested that blue-collar *production work* in many organizations is expanding to include more decision-making tasks than traditionally would have been part of a supervisory/managerial job. In addition, for some production workers, relatively narrow parameters of the job are giving way to broader involvement in work teams as well as interactions with external customers, clients, and patients. As team-based work structures have been used more widely, a number of studies have suggested that both cognitive and interactive skills are becoming more important in blue-collar jobs.

Technology is also having a significant impact on blue-collar jobs: for example, in some situations, replacing physical activity with mental and more abstract forms of responding. Generally, then, the implication of these changes is that information technology changes the mix of skills that are required, often creating jobs that require less sensory and physical skill and more "intellective" skills, such as abstract reasoning, inference, and cause–effect analysis (Committee on Techniques for the Enhancement of Human Performance, 2000).

For managerial jobs, the report suggested two interesting developments. First, at least lower level managers appear to be experiencing some loss in authority and control. Second, the need to communicate horizontally both within and across organizations may be becoming even more important than the supervision of an employee's work. There is also considerable discussion about the substantive content of managers' jobs, shifting toward the procurement and coordination of resources, toward coaching as opposed to commanding employees, and toward project management skills.

Within the service industry, the content of work is also evolving. First, a significant percentage of service jobs are becoming more routinized, in large measure because new information technologies enable greater centralization and control over work activities. Second, there is a tendency toward the blurring of sales and clerical jobs. Although the heterogeneity of work within specific service occupations appears to be increasing, this heterogeneity reflects, at least in part, the tendency to structure work differently according to market segments.

Interestingly, studies suggest a trend toward overall increase in technical skill requirements and cognitive complexity of service jobs. Although the initial impact of information technology involved a shift from manual to computer-mediated information processing, more recent applications involve the manipulation of a variety of software programs and databases. In addition, the rapid diffusion of access to the Internet has increased the potential for greater information-processing and cognitively complex activities. Finally, interpersonal interactions remain critical to service work, requiring skills in communications, problem solving, and negotiations.

With such changes becoming a more routine part of the work environment, to remain competitive, workers will likely need to upgrade their knowledge, skills, and abilities to avoid obsolescence, learning new systems and new activities at multiple points during their working lives. This may be particularly true for those workers who have been displaced from their jobs during economic downturns, only to find that those same jobs, once they are available again, may have different skill requirements from the old ones. In addition, over increased periods of unemployment, skills erode and behavior tends to change, leaving some people unqualified even for work they once did well (Peck, 2010). Because organizations increasingly operate in a wide and varied set of situations, cultures, and environments, not only may workers need to be more versatile and able to handle a wider variety of diverse and complex tasks, but employers will need to deal with an increasingly diverse workplace.

Recognizing that fundamentally new ways of thinking and acting will be necessary to meet the changing nature of work and worker requirements, organizations will be challenged to make wise and enduring decisions about how to attract, hire, and retain a skilled and motivated workforce. Historically, entry-level selection has centered on identifying skills important for performance early in a career. However, because finding and training workers in the future will be much more complex and costly than they are today, success on the job during and beyond the first few years will be increasingly important. The prediction of such long-term success indicators as retention and long-term performance will require the use of more complex sets of predictor variables that include such measures as personality, motivation, and vocational interest. To develop effective measures to predict long-term performance, it will be crucial to better understand the context of the workplace of the future, including the environmental, social, and group structural characteristics. Ultimately, combining the personal and organizational characteristics should lead to improved personnel selection models that go beyond the usual person–job relations, encouraging a closer look at theories of person–organization (PO) fit.

With the evolution of the workforce and the workplace in mind, the remainder of this chapter focuses on an examination of the evolving state of the science relevant to the future of worker recruitment, selection, and retention. We begin with a brief discussion of the activities required to identify the critical performance requirements of the job and the knowledge, skills, abilities, and other characteristics (KSAOs) that might be important to effective performance on the job.

## 2 JOB ANALYSIS AND JOB PERFORMANCE

### 2.1 Job Analysis

Job analysis identifies the critical performance requirements of the job and the KSAOs important to effective performance on the job; thus, it tells us what we should be looking for in a job candidate. Job analysis is a common activity with a well-defined methodology for conducting such analyses. As noted by Cascio (1995), terms such as *job element, task, job description*, and *job family* are well understood. Although job analysis continues to be an important first step in selection research and practice, the changing nature of work may suggest some movement in the future from a focus

on discrete job components to a more process-oriented approach.

A major development over the last decade or so in job analysis is a Department of Labor initiative to analyze virtually all jobs in the U.S. economy in order to build a database of occupational information (O*NET). This database may be used by organizations and individuals to help match people with jobs. The person–job (PJ) fit feature of the O*NET enables comparisons between personal attributes and targeted occupational requirements. There is also an organizational–characteristics component that facilitates PO matches. The hope is that O*NET will help unemployed workers and students entering the workforce to find more appropriate jobs and careers and employers to identify more highly qualified employees. These matches should be realized more systematically and with more precision than has been possible heretofore. An additional hope is that this initiative will encourage research that further advances the effectiveness of PJ matching, PO fit, and the science of personnel selection (Borman et al., 2003).

## 2.2 Job Performance Domain

A central construct of concern in work psychology is job performance, because performance criteria are often what we attempt to predict from our major interventions, including personnel selection, training, and job design. Traditionally, while most attention has focused on models related to predictors (e.g., models of cognitive ability, personality, and vocational interests), job performance models and research associated with them are beginning to foster more scientific understanding of criteria.

For example, Hunter (1983), using a path-analytic approach, found that cognitive ability has primarily a direct effect on individuals' acquisition of job knowledge. Job knowledge, in turn, influenced technical proficiency. Supervisory performance ratings were a function of both job knowledge and technical proficiency, with the job knowledge–ratings path coefficient three times as large as the technical proficiency–ratings coefficient. This line of research continued, with additional variables being added to the models. Schmidt et al. (1986) added job experience to the mix; they found that job experience had a direct effect on the acquisition of job knowledge and an indirect effect on task proficiency through job knowledge.

Later, Borman et al. (1991) included two personality variables, achievement and dependability, and behavioral indicators of achievement and dependability. The path model results showed that the personality variables had indirect effects on the supervisory performance ratings through their respective behavioral indicators. The best-fitting model also had paths from ability to acquisition of job knowledge, job knowledge to technical proficiency, and technical proficiency to the supervisory job performance ratings, arguably the most comprehensive measure of overall performance. Perhaps the most important result of this study was that the variance accounted for in the performance rating exogenous (dependent) variable increased substantially with the addition of personality and the behavioral indicators of personality beyond that found with previous models, including ability along with job knowledge and technical proficiency.

### 2.2.1 Task and Contextual Performance

Another useful way to divide the job performance domain has been according to task and contextual performance. Borman and Motowidlo (1993) argued that organization members may engage in activities that are not directly related to their main task functions but nonetheless are important for organizational effectiveness because they support the "organizational, social, and psychological context that serves as the critical catalyst for task activities and processes" (p. 71). Borman and colleagues have settled on a three-dimensional system: (1) personal support, (2) organizational support, and (3) conscientious initiative (Coleman and Borman, 2000; Borman et al., 2001). The notion is to characterize the citizenship performance construct according to the recipient or target of the behavior: other persons, the organization, and oneself, respectively.

Thus, job performance criteria have always been important in personnel selection research, but a recent trend has been to study job performance in its own right in an attempt to develop substantive models of performance. The vision has been to learn more about the nature of job performance, including its components and dimensions, so that performance itself, as well as predictor–performance links, will be better understood. Again, if we can make more progress in this direction, the cumulative evidence for individual predictor construct/performance construct relationships will continue to progress and the science of personnel recruitment, selection, and retention will be enhanced substantially.

## 3 PERSONNEL RECRUITMENT

Personnel recruitment is an important first step in the science and practice of matching employer needs with individual talent. Prior to the economic downturn that developed in the latter half of the current decade, labor markets in many countries had become increasingly tight, requiring organizations to compete to attract talented jobseekers and fill job openings. This convinced many organizations of the importance of recruitment and led many organizations to increase their recruiting efforts to attract prospective applicants. In spite of recent economic conditions, an increased awareness of the importance of the positive impact of recruitment continues today.

In terms of filling vacancies, organizations have a choice between internal and external recruitment strategies. According to Ployhart et al. (2006), internal recruitment is generally preferred by organizations because of its reduced costs: reduced recruitment, socialization, and training costs; increased probability of success as the employee has already been deemed successful by the organization's performance appraisal; and reduced start-up time because the employee is already familiar with the organization and its policies.

When it comes to external recruitment, organizations have choices with regard to the sources they use.

### 3.1 Recruitment Sources

Considerable research has focused on the effectiveness of various recruitment methods, that is, how the organization is making potential applicants aware of the job opening (Breaugh et al., 2008). Zottoli and Wanous (2000) reviewed studies conducted on recruitment methods and found that referrals (individuals referred by a current employee) and direct applicants (walk-ins) were associated with lower turnover. More recently, Yakubovich and Lup (2006) found that the performance level of the referrer can be important such that referrals from higher performing employees were not only viewed by human resources (HR) personnel as having better qualifications, but also scored higher on an objective selection measure.

### 3.2 Recruiter Effects

Research on the effects of the recruiter on recruitment outcomes has been summarized by Chapman et al. (2005). They found that recruiter personableness was a strong predictor of job pursuit intentions ($r = 0.50$). Similarly, recruiter competence, trustworthiness, and informativeness were related to applicants' attraction to the organization. No other recruiter characteristics appear to be important; however, results of the Chapman et al. (2005) meta-analysis are based on a small number of studies and thus more research is needed.

### 3.3 Internet Recruitment

The topic of Internet recruitment has become very popular in the recruitment literature in recent years. This is not surprising considering that HR practitioners see the Internet and websites as effective recruitment sources (Chapman and Webster, 2003). Websites allow organizations to reach larger pools of applicants; however, as a downside, they can lead to adverse impact and privacy issues (Stone et al., 2005) and can attract a large number of unqualified applicants. Website features perceived as important to applicants are aesthetics, content, and their purpose (Breaugh et al., 2008). Online job boards (such as Monster.com and CareerBuilder.com) are also widely used by organizations and job applicants. Jattuso and Sinar (2003) found that industry/position-specific job boards appear to result in higher quality applicants.

### 3.4 Summary

The last decade has witnessed an increase in attention to personnel recruitment strategies. Research suggests that the recruitment method(s) used plays a role, as do certain personal characteristics of the recruiter in recruitment success. In particular, applicant perceptions of the recruiter's competence, trustworthiness, personableness, and amount of information offered are important variables. In addition, given the ubiquitous nature of the Internet in the lives of most applicants and organizations, its use has quickly become a major tool in recruitment efforts and should continue for the foreseeable future.

## 4 PERSONNEL SELECTION

An understanding of current thinking in personnel selection requires a focus on predictor measurement—in particular, ability, personality, vocational interests, and biodata—as well as a discussion of an alternative model to the traditional PJ fit selection strategy: namely, PO fit.

### 4.1 Predictor Measurement

#### 4.1.1 Ability

Abilities are relatively stable individual differences that are related to performance on some set of tasks, problems, or other goal-oriented activities (Murphy, 1996). Another definition, offered by Carroll (1993), conceptualizes abilities as relatively enduring attributes of a person's capability for performing a particular range of tasks. Although the term *ability* is widely used in both the academic and applied literature, several other terms have been related loosely to abilities. For example, the term *competency* has been used to describe individual attributes associated with the quality of work performance. In practice, lists of competencies often include a mixture of knowledges, skills, abilities, motivation, beliefs, values, and interests (Fleishman et al., 1999).

Another term that is often confused in the literature with abilities is *skills*. Whereas abilities are general traits inferred from relationships among performances of individuals observed across a range of tasks, skills are more dependent on learning and represent the product of training on particular tasks. In general, skills are more situational, but the development of a skill is, to a large extent, predicted by a person's possession of relevant underlying abilities, usually mediated by the acquisition of the requisite knowledge. That is, these underlying abilities are related to the rate of acquisition and final levels of performance that a person can achieve in particular skill areas (Fleishman et al., 1999).

Ability tests usually measure mental or cognitive ability but may also measure other constructs, such as physical abilities. In the following sections we discuss recent developments and the most current topics in the areas of physical ability testing, cognitive ability, and practical intelligence.

***Physical Abilities*** One important area for selection into many jobs that require manual labor or other physical demands is the use of physical ability tests. Most physical ability tests are performance tests (i.e., not paper and pencil) that involve demonstration of attributes such as strength, cardiovascular fitness, or coordination. Although physical ability tests are reported to be used widely for selection (Hogan and Quigley, 1994), not much new information has been published in this area in the past few years. In one study, Blakley et al. (1994) provided evidence that isometric strength tests are valid predictors across a variety of different physically demanding jobs and females scored substantially lower than males on these isometric strength tests. In light of these findings, there is a recent and growing interest in reducing adverse impact through pretest preparation. Hogan and Quigley (1994)

demonstrated that participation in a physical training program can improve females' upper body strength and muscular endurance and participation in a pretest physical training program was significantly related to the likelihood of passing a firefighter physical ability test.

***Cognitive Ability*** In the early twentieth century, Cattell, Scott, Bingham, Viteles, and other applied psychologists used cognitive ability tests to lay the foundation for the current practice of personnel selection (Landy, 1993). Recent attention has focused on the usefulness of general cognitive ability *g* versus more specific cognitive abilities for predicting training and job performance and the contributions of information-processing models of cognitive abilities for learning more about ability constructs. First, there has been a debate concerning the "ubiquitousness" of the role of general cognitive ability, or *g*, in the prediction of training and job performance. Several studies have demonstrated that psychometric *g*, generally operationalized as the common variance in a battery of cognitive ability tests (e.g., the first principal component), accounts for the majority of the predictive power in the test battery and the remaining variance (often referred to in this research as "specific abilities") accounts for little or no additional variance in the criterion (e.g., Ree et al., 1994; Larson and Wolfe, 1995).

Other researchers have expressed concern related to the statistical model often used to define *g*. A general factor or *g* represents the correlations between specific ability tests, so specific abilities will, by definition, be correlated with the general factor. Thus, it could be argued that it is just as valid to enter specific abilities *first* and then say that *g* does not contribute beyond the prediction found with specific abilities alone (e.g., Murphy, 1996). In fact, Muchinsky (1993) found this to be the case for a sample of manufacturing jobs, where mechanical ability was the single best predictor of performance and an intelligence test had no incremental validity beyond the mechanical test alone.

We know very little about specific abilities when they are defined as the variance remaining once a general factor is extracted statistically. Interestingly, what little information is available suggests that these specific-ability components tend to be most strongly related to cognitive ability tests that have a large knowledge component (e.g., aviation information) (Olea and Ree, 1994). This is consistent with previous research showing that job knowledge tests tend to be slightly more valid than ability tests (Hunter and Hunter, 1984) and also with research demonstrating that job knowledge appears to mediate the relationship between abilities and job performance (e.g., Borman et al., 1993). Meta-analysis has demonstrated the generality of job knowledge tests as predictors of job performance (Dye et al., 1993). In addition, these authors found that the validity of job knowledge tests was moderated by job complexity and by job–test similarity, with validities significantly higher for studies involving high-complexity jobs and those with high job–test similarity.

***Practical Intelligence*** Sternberg and colleagues have attempted to broaden the discussion of general intelligence (Sternberg and Wagner, 1992). Based on a triarchic theory of intelligence, Sternberg (1985) suggested that practical intelligence and tacit knowledge play a role in job success. Practical intelligence is often described as the ability to respond effectively to practical problems or demands in situations that people commonly encounter in their jobs (Wagner and Sternberg, 1985; Sternberg et al., 1993). Conceptually, practical intelligence is distinct from cognitive ability. In fact, some research (Chan, 2001) has found measures of practical intelligence to be uncorrelated with traditional measures of cognitive ability.

Sternberg and his colleagues have repeatedly found significant correlations and some incremental validity (over general intelligence) for measures of tacit knowledge in predicting job performance or success (Sternberg et al., 1995). Tacit knowledge has been shown to be trainable and to differ in level according to relevant expertise. Certainly, tacit knowledge measures deal with content that is quite different from that found in traditional job knowledge tests (e.g., knowledge related to managing oneself and others).

***Summary*** A cumulation of 85 years of research demonstrates that if we want to hire people without previous experience in a job, the most valid predictor of future performance is general cognitive ability (Schmidt and Hunter, 1998). General cognitive ability measures have many advantages in personnel selection: (1) they show the highest validity for predicting training and job performance, (2) they may be used for all jobs from entry level to advanced, and (3) they are relatively inexpensive to administer. In addition, there is some evidence that measures of "practical intelligence" or tacit knowledge may under certain conditions provide incremental validity beyond general cognitive ability for predicting job performance (Sternberg et al., 1995). Finally, physical ability tests may be useful in predicting performance for jobs that are physically demanding.

### 4.1.2 Personality

Interest in personality stems from the desire to predict the motivational aspects of work behavior. Nevertheless, until recently, the prevalent view was that personality variables were a dead end for predicting job performance. Some of the factors fueling this belief were (1) the view that a person's behavior is not consistent across situations and thus that traits do not exist, (2) literature reviews concluding that personality variables lack predictive validity in selection contexts, and (3) concern about dishonest responding on personality inventories.

However, by the late 1980s, favorable opinions about personality regarding personnel selection began to grow (Hogan, 1991). Evidence accumulated to refute the notion that traits are not real (Kenrick and Funder, 1988) or stable (Conley, 1984). Research showed at least modest validity for some personality traits in predicting job performance (e.g., Barrick and Mount, 1991; McHenry et al., 1990; Ones et al., 1993). Further, evidence mounts that personality measures produce small, if any, differences between majority and protected

classes of people (Ones and Viswesvaran, 1998b) and that response distortion does not necessarily destroy criterion-related validity (e.g., Ones et al., 1996; Ones and Viswesvaran, 1998a).

Today's well-known, hierarchical, five-factor model (FFM) of personality (alternatively, "the Big Five") was first documented in 1961 by Tupes and Christal (see Tupes and Christal, 1992). The five factors were labeled *surgency*, *agreeableness*, *dependability*, *emotional stability*, and *culture*. Following Tupes and Christal, McCrae and Costa (1987) replicated a similar model of the FFM. In their version, *extraversion* is comprised of traits such as talkative, assertive, and active; *conscientiousness* includes traits such as organized, thorough, and reliable; *agreeableness* includes the traits kind, trusting, and warm; *neuroticism* includes traits such as nervous, moody, and temperamental; and *openness* incorporates such traits as imaginative, curious, and creative (Goldberg, 1992).

A large amount of evidence supports the generalizability and robustness of the Big Five. Others argue that the theoretical value and the practical usefulness of the Big Five factors are severely limited by their breadth *and* important variables are missing from the model. From an applied perspective, important questions pertain to the criterion-related validity of personality variables and the extent to which it matters whether we focus on broad factors or narrower facets.

Although the Big Five model of personality is not universally accepted, considerable research has been conducted using this framework. For example, Barrick et al. (2001) conducted a second-order meta-analysis including 11 meta-analyses of the relationship between Big Five personality dimensions and job performance. They included six performance criteria and five occupational groups. Conscientiousness was a valid predictor across all criteria and occupations ($\rho$ values of 0.19–0.26), with the highest overall validity of the Big Five dimensions. Emotional stability was predictive for four criteria and two occupational groups. Extraversion, agreeableness, and openness did not predict overall job performance, but each was predictive for some criteria and some occupations. Barrick et al.'s results echoed conclusions of previous research on this topic (e.g., Barrick and Mount, 1991; Hurtz and Donovan, 2000).

Despite the low to moderate magnitude of the Big Five's predictive validity, optimism regarding personality's usefulness in selection contexts remains high. One reason is that even a modestly predictive variable, if uncorrelated with other predictors, offers incremental validity. Personality variables tend to be unrelated to tests of general cognitive ability ($g$) and thus they have incremental validity over $g$ alone (Day and Silverman, 1989; Hogan and Hogan, 1989; McHenry et al., 1990; Schmitt et al., 1997). For example, conscientiousness produces gains in validity of 11–18 % compared to using $g$ alone (Salgado, 1998; Schmidt and Hunter, 1998). Salgado (1998) reported that emotional stability measures produced a 10 % increment in validity over $g$ for European civilian and military samples combined. For military samples alone, the incremental validity was 38 %.

**Compound Traits: Integrity, Adaptability, and Core Self-Evaluation** In contrast to considering links between narrow personality traits and individual job performance criteria, a very different approach for personality applications in personnel selection is the development of *compound traits*. Compound traits have the potential to show even stronger relationships with criteria because they are often constructed by identifying the criterion first and then selecting a heterogeneous group of variables expected to predict it (Hogan and Ones, 1997). Integrity, adaptability, and core self-evaluation are three compound traits that may be especially useful in a selection context.

Integrity consists of facets from all Big Five factors: mainly conscientiousness, agreeableness, and emotional stability (Ones et al., 1994). Integrity tests have several advantages as part of selection systems, including considerable appeal to employers. Because of the enormous costs of employee theft and other counterproductive behaviors (U.S. Department of Health and Human Services, 1997; Durhart, 2001), it is understandable that employers want to avoid hiring dishonest applicants. Also, paper-and-pencil integrity measures have grown in popularity since the 1988 Federal Polygraph Protection Act banned most preemployment uses of the polygraph test. Empirical evidence shows that integrity tests are better than any of the Big Five at predicting job performance ratings ($\rho = 0.41$) (Ones et al., 1993). Under some conditions, integrity tests also predict various counterproductive behaviors at work. Integrity tests are uncorrelated with tests of $g$ (Hogan and Hogan, 1989; Ones et al., 1993) and produce a 27 % increase in predictive validity over $g$ alone (Schmidt and Hunter, 1998).

Adaptive job performance has become increasingly important in today's workplace. Existing personality scales carrying the adaptability label tend to be narrowly focused on a particular aspect of adaptability (e.g., International Personality Item Pool, 2001) and would probably not be sufficient to predict the multiple dimensions of adaptive job performance. One would expect that someone who readily adapts on the job is likely to be patient, even tempered, and confident (facets of emotional stability); open to new ideas, values, and experiences (facets of openness); and determined to do what it takes to achieve goals (a facet of conscientiousness). It is possible that high levels of other aspects of conscientiousness, such as dutifulness and orderliness, are detrimental to adaptive performance because they involve overcommitment to established ways of functioning. Again, although speculative, these relationships are in line with the results of several different studies that linked personality variables to adaptive performance (e.g., Mumford et al., 1993; Le Pine et al., 2000).

Core self-evaluation (CSE) is a fundamental, global appraisal of oneself (Judge et al., 1998). We should note that, whereas some have called CSE a compound trait, Judge and his colleagues might not agree with this characterization. Erez and Judge (2001) described CSE as a single higher order factor explaining the association among four more specific traits: self-esteem, generalized self-efficacy, internal locus of control, and

emotional stability. A meta-analysis showed that CSE's constituent traits are impressively predictive of overall job performance (Judge and Bono, 2001). Estimated $\rho$ values corrected for sampling error and criterion unreliability ranged from 0.19 (emotional stability) to 0.26 (self-esteem).

CSE is even more strongly related to job satisfaction than it is to overall job performance. Predictive validity estimates ranged from 0.24 (emotional stability) to 0.45 (self-efficacy) (Judge and Bono, 2001). People with high CSE seem to seek out challenging jobs and apply a positive mindset to the perception of their jobs (Judge et al., 1998, 2000). The result is desirable job characteristics, both real and perceived, which contribute to high job satisfaction. The link between CSE and job satisfaction has important implications, because satisfied employees are more likely to stay on the job than are dissatisfied employees (Tett and Meyer, 1993; Harter et al., 2002). Low turnover rates are especially important in organizations that invest heavily in the training of new employees.

**Summary**  Over the past two decades, personality has enjoyed a well-deserved resurgence in research and applied use, aided in part by the wide acceptance of the Big Five model of personality. These broad traits offer incremental predictive validity over cognitive ability alone (Salgado, 1998; Schmidt and Hunter, 1998). Using personality predictors narrower than the Big Five shows promise for revealing stronger criterion-related validities, especially when the criteria are relatively specific. Compound traits may be especially important in organizational environments that are more dynamic and team oriented (Edwards and Morrison, 1994). Complex, heterogeneous predictors are needed to predict the complex, heterogeneous performance criteria that are likely in such an environment.

Recent research has not only shown the criterion-related validity of personality but also addressed certain persistent objections to personality testing. Adverse impact appears not to be a problem. Response distortion, although certainly problematic in selection settings, may be alleviated with targeted interventions, although it still may be problematic with small selection ratios (i.e., a relatively low ratio of selectees) (Rosse et al., 1998). Also, considerable evidence exists to suggest that personality is impressively stable over the entire life span (Roberts and Del Vecchio, 2000). Thus, we can be confident that personality variables used in selection will predict performance of selectees throughout their tenure with an organization.

### 4.1.3 Vocational Interest

Needs, drives, values, and interests are closely related motivational concepts that refer to the intentions or goals of a person's actions. Interests are generally thought of as the most specific and least abstract of these concepts (Hogan and Blake, 1996). Hogan and Blake pointed out that vocational interests have not often been studied in relation to other motivational constructs. Holland and Hough (1976) suggested that a likely reason for this lack of attention to theoretical links with other constructs is the early empirical successes of vocational interest inventories, predicting outcomes such as vocational choice. In a sense, there was little reason to relate to the rest of psychology because of these successes. Accordingly, many psychologists have regarded the area of vocational interest measurement as theoretically and conceptually barren (Strong, 1943).

The most obvious link between vocational interests and relevant criteria appears to be between vocational interest responses and occupational tenure and, by extension, job satisfaction. For the most part, the tenure relation has been confirmed. For example, regarding occupational tenure, Strong (1943) demonstrated that occupational membership could be predicted by vocational interest scores on the Strong Vocational Interest Blank administered between 5 and 18 years previously. This finding at least implies that persons suited for an occupation on the basis of their interests tend to gravitate to and stay in that occupation.

For job satisfaction, the relationships are more mixed, but at best, the vocational interest/job satisfaction correlations are moderate (0.31). Vocational interests are not usually thought of in a personnel selection context, and in fact, there are not many studies linking vocational interests and job performance. Those that do exist find a median validity for interest predictors against job performance around 0.20. Although this level of validity is not very high and the number of studies represented is not large, the correlation observed compares favorably to the validities of personality constructs (e.g., Barrick and Mount, 1991).

Analogous to personality measures, vocational interest inventories used for selection have serious potential problems with slanting of responses or faking. It has long been evident that people *can* fake interest inventories (e.g., Campbell, 1971). However, some research has shown that in an actual selection setting applicants may not slant their responses very much (e.g., Abrahams et al., 1971).

Although the personality and vocational interest may be closely linked conceptually, it is evident that inventories measuring the two constructs are quite different. Personality inventories present items that presumably reflect the respondent's tendency to act in a certain way in a particular situation. Vocational interest items elicit like–dislike responses to objects or activities. There has been a fair amount of empirical research correlating personality and vocational interest responses. Hogan and Blake (1996) summarized the findings of several studies linking personality and vocational interests at the level of the Big Five personality factors and the six Holland types. Although many of these correlations are significant, the magnitude of the relationships is not very large. Thus, it appears that personality constructs and vocational interest constructs have theoretically and conceptually reasonable and coherent relationships but that these linkages are relatively small. What does this mean for selection research? Overall, examining vocational interests separately as a predictor of job performance (*and* job satisfaction and attrition) seems warranted.

**Summary**  Vocational interest measures, similar to personality measures, tap motivation-related constructs.

Interests have substantial conceptual similarity to personality, but empirical links between the two sets of constructs are modest. Vocational interest measures are most often used in counseling settings and have been linked primarily to job satisfaction criteria. However, although not often used in a selection context, limited data suggest reasonable levels of validity. Accordingly, vocational interests may show some promise for predicting job performance.

### 4.1.4 Biodata

The primary principle behind the use of biodata is that the best predictor of future behavior is past behavior. In fact, biodata offer a number of advantages when used in personnel selection. Among the most significant is their power as a predictor across a number of work-related criteria. For example, in a meta-analytic review of over 85 years of personnel psychology research, Schmidt and Hunter (1998) reported mean biodata validity coefficients of 0.35 and 0.30 against job and training success, respectively. These findings support previous research reporting validities ranging from 0.30 to 0.40 between biodata and a range of criteria, such as turnover, absenteeism, job proficiency, and performance appraisal ratings (e.g., Asher, 1972; Reilly and Chao, 1982; Hunter and Hunter, 1984). Based on these meta-analytic results, researchers have concluded that biographical inventories have almost as high validities as cognitive ability tests (Reilly and Chao, 1982). In addition, research indicates that biodata show less adverse impact than that of cognitive ability tests (Wigdor and Garner, 1982). Importantly, the high predictability associated with biodata, the ease of administration of biodata instruments, the low cost, and the lack of adverse impact have led to the widespread use of biodata in both the public and private sectors (Farmer, 2001).

Mael (1991) reviewed certain ethical and legal concerns that have been raised about biodata. The first of these deals with the controllability of events. That is, there are actions that respondents choose to engage in (controllable events), whereas other events either are imposed upon them or happened to them (noncontrollable events). Despite the belief held by numerous biodata researchers that all events, whether or not controllable, have the potential to influence later behavior, some researchers (e.g., Stricker, 1987, 1988) argue that it is unethical to evaluate individuals based on events that are out of their control (e.g., parental behavior, socioeconomic status). As a result, some have either deleted all noncontrollable items from their biodata scales or created new measures with the exclusion of these items. A frequent consequence, however, is that using only controllable items reduces the validity of the biodata instrument (Mael, 1991).

Two other ethical and legal concerns that have been raised are equal accessibility and invasion of privacy. That is, some researchers (e.g., Stricker 1987, 1988) argue that items dealing with events not equally accessible to all individuals (e.g., playing varsity football) are inherently unfair and should not be included. Similarly, the current legal climate does not encourage the use of items perceived as personally invasive. Overall,

minimizing such issues as invasiveness might be encouraged. What should be especially avoided, however, is a reliance on subjective and less verifiable items that compromise the primary goal of retrieving relatively objective, historical data from applicants.

**Summary**   Biodata predictors are a powerful noncognitive alternative to cognitive ability tests that have shown significant promise as a predictor in selection. The principle relative to biodata is that past behaviors matter and should be taken into account when criteria such as performance, absenteeism, and other work-related outcomes are being predicted. In addition, efforts are currently under way to develop a more theoretical understanding of the constructs involved with biodata. Finally, ethical and legal concerns are being addressed in hopes of creating an acceptable compromise between high predictability and overall fairness. Thus, although there is still much to be done in understanding how past behaviors can be used in personnel selection, evidence suggests that enhancing biodata techniques seems like a step in the right direction. Some examples of published tests that measure many of the predictor constructs discussed in the preceding section are given in Table 1.

## 4.2   Person–Organization Fit

Conventional selection practices are geared toward hiring employees whose KSAOs provide the greatest fit with clearly defined requirements of specific jobs. The characteristics of the organization in which the jobs reside, those characteristics of the person relative to the organization as a whole, are rarely considered. The basic notion with PO fit is that a fit between personal attributes and characteristics of the target organization contributes to important positive individual and organizational outcomes.

### 4.2.1   Attraction–Selection–Attrition

Much of the recent interest in the concept of PO fit can be traced to the attraction–selection–attrition (ASA) framework proposed by Schneider (e.g., Schneider, 1987, 1989; Schneider et al., 2000). Schneider (1987) outlined a theoretical framework of organizational behavior based on the mechanism of person–environment fit that integrates both individual and organizational theories. It suggests that certain types of people are attracted to and prefer particular types of organizations; organizations formally and informally seek certain types of employees to join the organization; and attrition occurs when employees who do not fit a particular organization leave. Those people who stay with the organization, in turn, define the structure, processes, and culture of the organization.

Van Vianen (2000) argued that, although many aspects of organizational life may be influenced by the attitudes and personality of the employees in the organization, this does not necessarily require that the culture of a work setting originate in the characteristics of people. He suggested, instead, that cultural dimensions reflecting the human side of organizational life are more adaptable to characteristics of people, whereas cultural

**Table 1 Sampling of Tests That Measure Predictor Constructs**

| Test | Publisher | Construct/Focus |
|---|---|---|
| Achievement and Success Index | LIMRA | Biodata |
| Adaptability Test | Pearson Reid London House | Adaptability |
| Basic Skills Test | Psychological Services, Inc. | Cognitive abilities |
| California Psychological Inventory | CPP | Personality |
| Differential Aptitude Tests | Harcourt Assessment | Cognitive abilities |
| Employee Aptitude Survey | Harcourt Assessment | Cognitive abilities |
| Hogan Personality Inventory | Hogan Assessment Systems | Personality |
| Management Interest Inventory | SHL | Managerial interests |
| NEO Five-Factor Inventory | PAR | Personality |
| Myers–Briggs Type Indicator | CPP | Personality |
| MPTQ | Proctor & Gamble | Biodata |
| Physical Ability Test | FSI | Physical abilities |
| Self-Directed Search | PAR | Vocational interest |
| Strong Interest Inventory | CPP | Vocational interest |
| Watson–Glaser Critical Thinking | Harcourt Assessment | Cognitive abilities |

dimensions that reflect the production side of organizational life are more determined by organizational goals and the external environment.

Similarly, Schaubroeck et al. (1998) proposed that a more complex conceptualization of the ASA process that incorporates the distinction between occupational and organizational influences should be examined more closely. These researchers investigated the role of personality facets and PO fit and found that personality homogenization occurs differently and more strongly within particular occupational subgroups within an organization. Similarly, Haptonstahl and Buckley (2002) suggested that as work teams become more widely used in the corporate world, person–group (PG) fit becomes an increasingly relevant construct.

### 4.2.2 Toward an Expanded Model of Fit and a Broader Perspective of Selection

The research and theorizing reported in this section suggest that selection theory should consider making fit assessments based PJ fit, PO fit, and PG fit. Traditional selection theory considers PJ fit as the basis for selecting job applicants, with the primary predictor measures being KSAOs and the criterion targets being job proficiency and technical understanding of the job.

To include PO fit as a component of the selection process, one would evaluate applicants' needs, goals, and values. The assumptions here are that the greater the match between the needs of the applicant and organizational reward systems, the greater the willingness to perform for the organization, and the greater the match between a person's goals and values and an organization's expectations and culture, the greater the satisfaction and commitment.

Finally, at a more detailed level of fit, there is the expectation that suborganizational units such as groups may have different norms and values than the organization in which they are embedded. Thus, the degree of fit between an individual and a group may differ significantly from the fit between the person and the organization. PG fit has not received as much research attention as either PJ fit or PO fit, but it is clearly different from these other types of fit (Kristof, 1996; Borman et al., 1997).

Werbel and Gilliland (1999) suggested the following tenets about the three types of fit and employee selection: (1) the greater the technical job requirements, the greater the importance of PJ fit; (2) the more distinctive the organizational culture, the greater the need for PO fit; (3) the lengthier the career ladder associated with an entry-level job, the greater the importance of PO fit; (4) the more frequent the use of team-based systems within a work unit, the greater the importance of PG fit; and (5) the greater the work flexibility within the organization, the greater the importance of PO fit and PG fit.

### 4.2.3 Summary

When jobs and tasks are changing constantly, the process of matching a person to some fixed job requirements becomes less relevant. Whereas traditional selection models focused primarily on PJ fit, several have argued that with new organizational structures and ways of functioning individual–organizational fit and individual–group fit become more relevant concepts. In our judgment, selection models in the future should incorporate all three types of fit as appropriate for the target job and organization. We can conceive of a hybrid selection model where two or even all three types of fit are considered simultaneously in making selection decisions. For example, consider the possibility of a special multiple-hurdle application in which, in order to be hired, applicants must have above a level of fit for the initial job, the team to which they will first be assigned, *and* the target organization. *Or*, depending on the particular selection context for an organization, the three types of fit might be weighted differentially in selecting applicants. Obviously, the details of hybrid selection models such as these have yet

to be worked out. However, the notion of using more than one fit concept seems to hold promise for a more flexible and sophisticated approach to making selection decisions.

## 5  PERSONNEL TURNOVER

The retention of high-quality employees is a strategic priority for contemporary organizations, as turnover can impact firm performance (Glebbeek and Bax, 2004; Kacmar et al., 2006), quality of customer service (Schlesinger and Heskett, 1991), and turnover among remaining employees. In addition, according to Cascio (2000), other turnover costs include *separation costs* (e.g., costs of the exit interview, separation benefits, vacancy costs), *replacement costs* (costs of replacing the leaver: recruitment and selection), and *training costs* (orientation and training for new employees). Regarding a typology of turnover, we can distinguish between involuntary and voluntary turnover (Hom and Griffeth, 1995). Involuntary turnover refers to job separations initiated by the organization (such as firings and layoffs). Voluntary turnover refers to turnover initiated by the employee. A further differentiation of voluntary turnover can be made between functional (turnover of low performers) and dysfunctional (the turnover of high performers).

### 5.1  Reducing Voluntary Turnover

Efforts to reduce turnover can begin before employees enter the organization in the recruitment and personnel selection stages. In the recruitment stage, a useful tool for reducing turnover is the realistic job preview (RJP). RJPs are comprehensive profiles of both the positive and negative features of a job presented by the organization to prospective or new employees. RJPs are hypothesized to work by reducing the unrealistic expectations new employees may have. In a meta-analytic review, Philips (1998) found that RJPs were successful in reducing attrition from the recruitment process, fostering accurate initial expectations, and reducing all types of turnover once on the job, including voluntary turnover. In addition, RJPs were related to job performance, although the mean correlation was only 0.05. RJPs are considered most effective when given in the recruitment stage (Philips, 1998; Wanous, 1980), although they can be administered to new employees during the socialization stage as well.

Efforts to reduce turnover can also be made in the personnel selection stage. For example, in a rare longitudinal study using actual job applicants, Barrick and Zimmerman (2005) found that self-confidence and decisiveness and a biographical measure (consisting of tenure in the previous job, the number of family and friends in the organization, and whether the applicant was referred by a current employee of the organization) were predictive of voluntary turnover six months later. Meta-analytic reviews confirmed that weighted application blanks are predictive of employee turnover (Hom and Griffeth, 1995; Griffeth et al., 2000). Similarly, Barrick and Mount (1996) found that conscientiousness was negatively related to employee turnover. Carefully developed structured employment interviews have also been found to predict turnover, with a corrected correlation of 0.39 for an empirically based telephone administered interview (Schmidt and Rader, 1999).

A variety of interventions can be used to reduce turnover after employees have joined the organization. McEvoy and Cascio (1985) conducted a meta-analysis of the strategies used by organizations to reduce turnover. In addition to RJPs discussed above, they found that job enrichment strategies (such as increasing decision making, task variety, and autonomy) were successful in reducing turnover. In fact, they found that job enrichment strategies were about twice as effective as RJPs at reducing turnover. An intervention to improve retention in the U.S. Army involved a unit retention climate feedback system that surveyed unit members about their shared perceptions relevant to soldier retention decisions in the unit. Part of the system was a unit leadership feedback report based on the survey responses that provided actionable guidance for leaders to use to improve the unit's retention climate to in turn enhance reenlistement rates (Kubisiak et al., 2009). Turnover can also be reduced indirectly by increasing employees' job satisfaction and organizational commitment (Griffeth et al., 2000).

Research has begun to recognize that outside work factors (e.g., factors related to the community) can impact voluntary turnover. About 10 years ago, Mitchell et al. (2001) introduced job embeddedness as a construct focused on the factors that influence a person's staying on a job. Job embeddedness has three dimensions: links, fit, and sacrifice, which are relevant to both the organization and the community. Job embeddedness has been found to be predictive of voluntary turnover (Mitchell et al., 2001). More importantly, Mitchell et al. (2001) found that job embeddedness has incremental validity over measures of job satisfaction, organizational commitment, and perceived alternatives. Lee et al. (2004) distinguished between two major subdimensions of job embeddedness: on the job and off the job. They report that only off-the-job embeddedness (e.g., links to and fit with the community) was predictive of voluntary turnover.

### 5.2  Summary

Because of the financial costs and the potential loss of critical organizational knowledge when valued employees leave the organization, personnel turnover and retention are a critical focus for organizations. Research points to the importance of prospective employers offering a realistic job preview to applicants as a vital first step in strengthening the employee–employer relationship. Using proper predictor measures that allow identification of applicants with the necessary job-related attributes is also crucial. Beyond use of these recruitment and selection strategies, creating the right climate where employees feel they will be able to work productively and develop professionally will increase the chances that employees will choose to remain with the organization rather than seek employment elsewhere.

## 6 CONCLUSION

The world of work is in the midst of profound changes that will require new thinking about personnel selection. Workers will probably need to be more versatile, handle a wider variety of diverse and complex tasks, and have more sophisticated technological knowledge and skills. The aim of this chapter was to provide a review of the state of the science on personnel recruitment, selection, and turnover research and thinking. Accordingly, we reviewed research on performance criteria and provided a review of recruitment strategies; predictor space issues, including predictors that tap such domains as ability, personality, vocational interests, and biodata; selection issues related to PJ match and PO fit; and, finally, turnover and retention strategies.

Relative to criterion measurement, research has demonstrated that short-term, technical performance criteria are best predicted by general cognitive ability, whereas longer term criteria such as nontechnical job performance, retention, and promotion rates are better predicted by other measures, including personality, vocational interest, and motivation constructs. To select and retain the best possible applicants, it would seem critical to understand, develop, and evaluate multiple measures of short- and long-term performance as well as other indicators of organizational effectiveness, such as turnover/retention.

Recruitment emphasis has increased over the last decade, with research noting the importance of recruitment methods and recruiter characteristics. In addition, organizations are increasingly taking advantage of internet and Web-based recruitment tools for targeting qualified applicants. As use of these techniques continues to grow, associated research will accumulate to assess their effectiveness.

On the predictor side, advances in the last decade have shown that we can reliably measure personality, motivational, and interest facets of human behavior and that under certain conditions these can add substantially to our ability to predict turnover, retention, and job performance. The reemergence of personality and related volitional constructs as predictors is a positive sign in that this trend should result in a more complete mapping of the KSAO requirements for jobs and organizations, beyond general cognitive ability.

We would also recommend that organizations consider ways of expanding the predictor and criterion domains that result in selecting applicants with a greater chance of long-term career success, and when doing so, it will be important to extend the perspective to broader implementation issues that involve classification of personnel and PO fit. As organizational flexibility in effectively utilizing employees increasingly becomes an issue, the PO fit model may be more relevant compared to the traditional PJ match approach.

Finally, in order to combat the potential loss of critical organizational knowledge when valued employees leave the organization, personnel turnover and retention remains a critical focus for organizations. Use of effective recruitment and hiring strategies as well as creating the right climate where employees feel they will be able to work productively and develop professionally will help to embed individuals in the culture of the organization and increase the chances that they will remain.

# CHAPTER 17

# DESIGN, DELIVERY, EVALUATION, AND TRANSFER OF TRAINING SYSTEMS

**Chris W. Coultas, Rebecca Grossman, and Eduardo Salas**
University of Central Florida
Orlando, Florida

## 1 INTRODUCTION

Training is a key component to the life of the modern organization. Various instructional strategies, learning options, and technologies have made the training industry larger and more diverse than ever. The American Society for Training and Development notes in their "State of the Industry Report" (Paradise and Patel, 2009) that organizations, on average, spent $1068 and allotted 36.3 h per employee for learning and development efforts in 2008. While this represents a 3.8% monetary decrease from 2007, due largely to the worldwide economic downturns, it is a 30% increase from 2003 to 2004, when organizations spent approximately $820 per employee (Sugrue and Rivera, 2005). These individual training expenses aggregate to an astounding $134.07 billion spent on employee training in 2008. Considering organizations invest so much in training, it follows that training should be designed in such a way as to maximize its effectiveness. Not only can proper training be a boon to organizations, but improper training can have severely negative consequences, and effective training can help mitigate these. At the most dramatic, improper (or lack of) training can lead to injury or death—as early as 2001, reports indicated the $131.7 billion was spent annually due to employee injuries and death (National Safety Council); these figures increased to $183.0 billion during 2008 (National Safety Council, 2010).

Training can, and does, differ greatly in regards to specific emphases (e.g., prevent accidents, improve service, create better products), and these generally vary depending on the organization. However, the universal goal of training is to improve the quality of the workforce so as to strengthen the bottom line of the organization. If this is to happen, training designers and providers must take advantage of the ever-growing field of training research (Aguinis and Kraiger, 2009; Salas and Cannon-Bowers, 2001) and apply it to the analysis, design, delivery, evaluation, and transfer of training systems. Therefore, this chapter will outline the relevant research on what constitutes an effective training system. To this end, we have updated the Salas and colleagues (2006b) "design, delivery, and evaluation of training systems" and incorporated a vast amount of recent work on training into the review (e.g., Kozlowski and Salas, 2010; Aguinis and Kraiger, 2009; Sitzmann et al., 2008; Burke and Hutchins, 2007).

## 1.1 Training Defined

While training has been shown to generally have positive effects on individual and organization levels, it is vital for an overview of the training literature to begin with a definition of what training is. At its most basic level, training can be defined as any systematic efforts to impart knowledge, skills, attitudes,[*] or other characteristics with the end goal being seeing improved performance. To achieve this broad goal, training must change some (or all) of the following characteristics of the trainee: knowledge, patterns of cognition, attitudes, motivation, and abilities. However, this cannot occur if training is designed and delivered haphazardly and with general disregard to the scientific principles of training. Training efforts must have a keen eye toward the science of training and learning—it must provide opportunities to not only *learn* the necessary knowledge, skills, attitudes, and other characteristics (KSAOs) but also practice and apply this learning and receive feedback regarding these attempts within the training (Salas and Cannon-Bowers, 2000a; Aguinis and Kraiger, 2009).

In today's rapidly expanding technological landscape, it is the tendency of individuals to nearly automatically accept the newest technology in training as the best or most appropriate. However, technological advances do not necessarily equate to psychological advances, and many times, training strategies independent of advanced technology have proven to be just as effective (if not more so) than their more advanced counterparts. This is discussed in greater detail later in the chapter, but this serves to illustrate the point that the elements of training have a very real scientific basis.

Chen and Klimoski (2007) recently reviewed the literature on training and development, and their qualitative findings should be encouraging to researchers and practitioners alike. They state that the current literature regarding training is, on the whole, scientifically rigorous and has "generated a large body of

knowledge pertaining to learning antecedents, processes, and outcomes" (p.188). This is a major improvement over earlier literature reviews describing then-current research on training as "nonempirical, nontheoretical, poorly written, and dull" (Campbell, 1971, p. 565). While research avenues in the field of training are by no means exhausted, theories, models, and frameworks provide effective guidelines for developing and implementing training programs (Salas and Cannon-Bowers, 2001). These theories and frameworks are described and referenced throughout this chapter.

## 2 SCIENCE OF TRAINING: THEORETICAL DEVELOPMENTS

It has been said that there is "nothing more practical than a good theory" (Lewin, 1951). This timeless quote illustrates the fact that, while some emphasize a divide between basic and applied research or between academia and industry, it is empirically grounded theory that enables practitioners to design, develop, and deliver training programs with confidence. Accordingly, we do not overlook the theoretical underpinnings that drive the science and practice of training. In the previous review by Salas and colleagues (2006b), we identified the transfer of training as a developing area of research we deemed important to include in our discussion of training. Prominent models of transfer and training effectiveness were depicted and described. Since that time, training scholars have made additional strides toward our understanding of the training process. The role of transfer continues to be emphasized in theoretical models and empirical studies. Transfer models have been supplemented and revised. Updated models of training effectiveness have also been proposed. In the following paragraphs, we briefly review the training theories we previously described and discuss theoretical developments that have since occurred.

If the ultimate goal of training is to see positive organizational change, trainees must be able to transfer what they have learned in the training environment and apply it to work within the organizational setting. Accordingly, it is vital for researchers and practitioners alike to understand under what contexts this transfer of training is likely to occur. Recent research continues to support Thayer and Teachout's (1995) widely accepted model of training transfer outlined in the previous review (Salas et al., 2006b). The factors they identified as maximizing transfer have been separately supported within the literature and include trainee: (1) reactions to previous training (Baldwin and Ford, 1988), (2) education (Mathieu et al., 1992), (3) pretraining self-efficacy (Ford et al., 1992), (4) ability (Ghiselli, 1966), (5) locus of control (Williams et al., 1991), (6) job involvement (Noe and Schmitt, 1986), and (7) career/job attitudes (Williams et al., 1991). Additionally, trainee reactions to the training/task at hand regarding overall likability (Kirkpatrick, 1976), perceived instrumentality of training (Velada et al., 2007), and expectancy that transfer can/will occur (i.e., self-efficacy, Latham, 1989; Tannenbaum et al., 1991) have all been shown to lead to

---

[*] Although much of the literature refers to the "A" of KSAOs as abilities (e.g., Goldstein, 1993), in this chapter we refer to the "A" as attitudes.

greater training transfer. Furthermore, organizational climate and transfer-enhancing activities can facilitate the transfer of training. In fact, a recent meta-analysis (Blume et al., 2010) showed that an organizational climate that supports training efforts is the most important aspect of the work environment in predicting training transfer. Organizational cues and consequences can encourage transfer. Transfer-enhancing activities such as goal setting, relapse prevention, self-management (Baldwin et al., 2009), and job aids can assist the trainee in applying learning in the long term. The final factor in the Thayer and Teachout (1995) model is results; transfer of training should be evaluated in the context of whether learned knowledge translates into workplace behavior and whether behavioral change leads to organizationally desirable results.

More recently, Burke and Hutchins (2008) proposed a model of transfer based on a major review of the training literature. The model, though simple, effectively summarizes much of the research on training, as it identifies personal (i.e., trainer/trainee), training (e.g., design, content), and environmental (i.e., organizational) characteristics as all having significant effects on training transfer. Furthermore, various aspects are seen as having greater impact at various times in the life cycle of training (e.g., trainer characteristics are more salient pretraining, organizational characteristics are more salient posttraining). See Figure 1 for the full model.

Recent research has emphasized that training is a multifaceted phenomenon, consisting of complex interactions between trainee, trainer, organization, and the

training itself. Bell and Kozlowski (2008) developed a model that reflects many of these interactions. Their model outlines the various interactions necessary to see trainees gain knowledge and transfer that knowledge to the workplace. While the model excludes some important aspects of the training experience, most notably organizational characteristics, it shows the impact that individual characteristics (i.e., cognitive ability, motivation, personality, etc.) can have on training design choices (i.e., error framing, exploratory learning) and how they interact to affect learning and training outcomes. Another major advantage of this model is that Bell and Kozlowski empirically verified their model using structural equation modeling. Their theoretical model is replicated in Figure 2, but a more complex version, complete with correlation indices, is included in Bell and Kozlowski (2008).

An incredibly in-depth examination of the factors and processes involved in training provided by Tannenbaum and colleagues (1993; Cannon-Bowers et al., 1995) was described in the previous review and remains relevant in current discussions of the training process (Figure 3). The framework considers training from a longitudinal, process-oriented perspective. Similarities between this model and the Burke and Hutchins (2008) model are apparent; however, this model is much more detailed. Additionally, this model identifies vital actions to ensure training success (e.g., training needs analysis).

Mathieu and Tesluk (2010) recently described a multilevel perspective of training effectiveness in which several levels of analysis are considered. In this view,

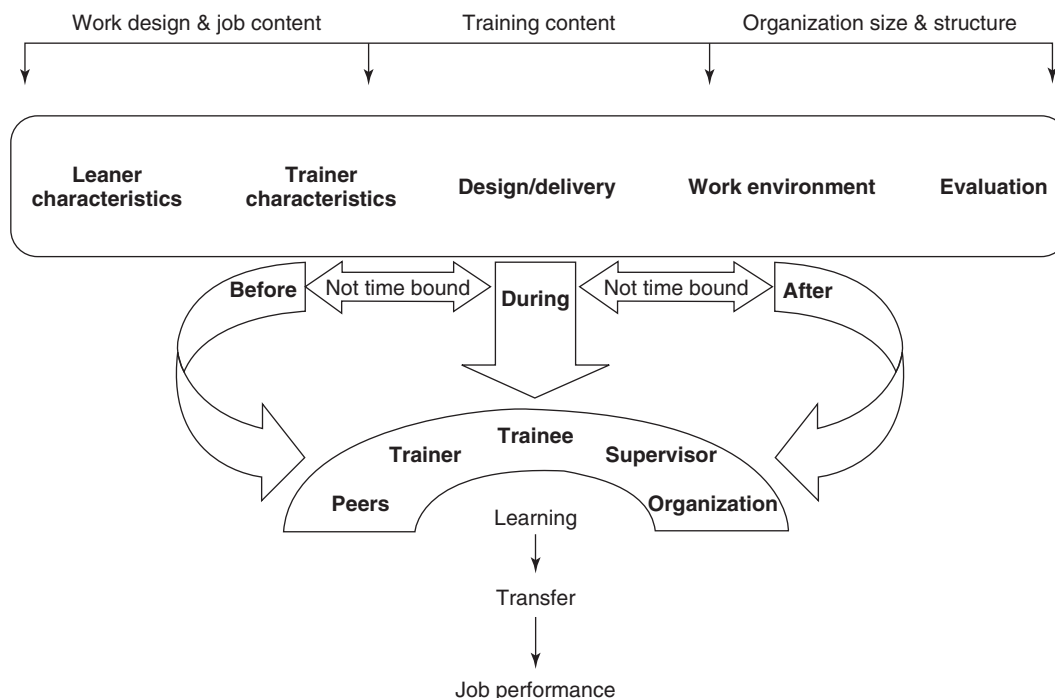

**Figure 1**   Transfer model. (From Burke and Hutchins, 2008.)
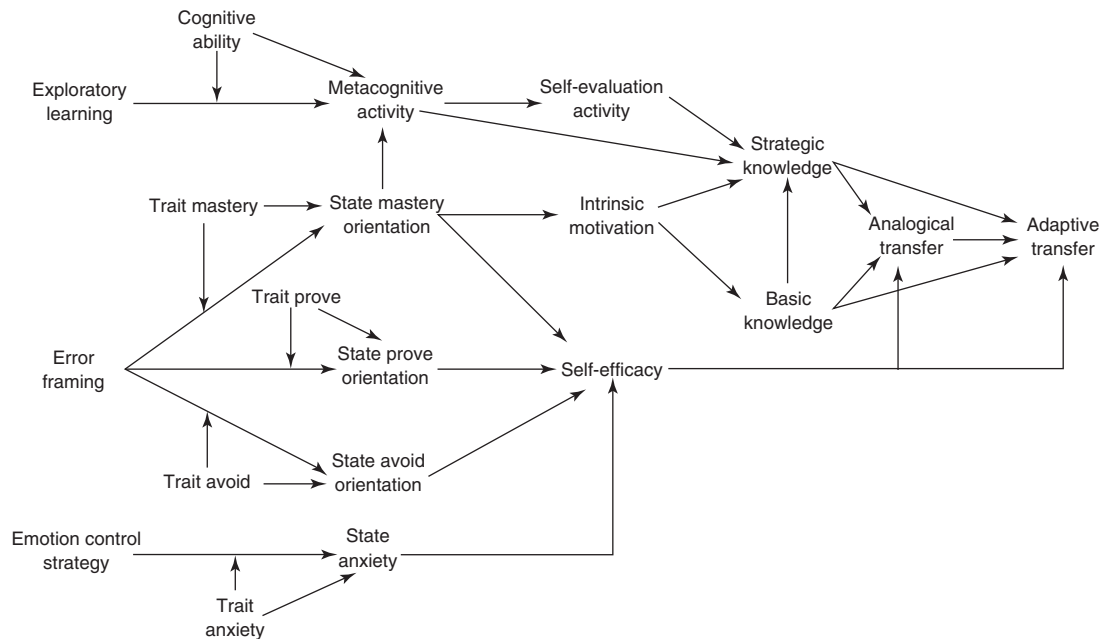

**Figure 2** Transfer model (From Bell and Kozlowski, 2008).

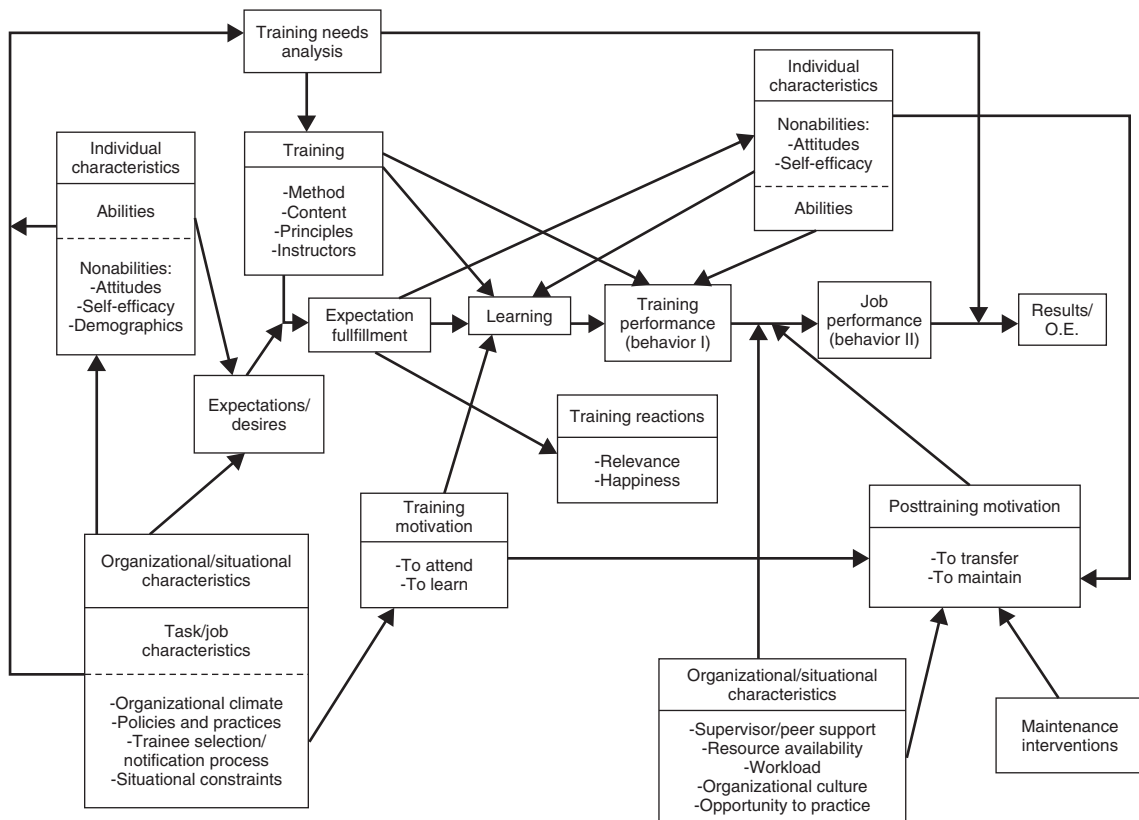

**Figure 3** Training effectiveness model. (From Tannenbaum et al., 1993; Cannon-Bowers et al., 1995.)

training outcomes result from the combined influences of various organizational levels (e.g., individuals, work-groups, departments). Further, unlike other multilevel approaches, the current framework incorporates both bottom-up (e.g., factors at the training level) and top-down (e.g., factors at the organizational level) influences on training effectiveness. Further, microlevel outcomes such as the specific KSAOs that are developed and macrolevel outcomes such as broader organizational outcomes are considered. Finally, the multilevel perspective put forth by Mathieu and Tesluk (2010) considers the combined effects of training and other human resource interventions (i.e., compilation approach) as well as the impact of organizational factors on individual-level training outcomes (i.e., cross-level approach). A visual representation of this approach is depicted in Figure 4.

Specific issues relevant to training, such as motivation (Colquitt et al., 2000; Chiaburu and Lindsay, 2008), individual characteristics and work environment (Tracey et al., 2001; Bell and Kozlowski, 2008), learner control (Sitzmann et al., 2008), training evaluation (Kraiger et al., 1993), and transfer of training (Quinones, 1997; Burke and Hutchins, 2007), have been studied extensively. The increasing reliance on teams in organizations has also led to a focus on team training. Kozlowski and colleagues (2000) explored how training and individual processes lead to team and organizational outcomes. Other models throughout the past decade or more have examined the factors of organizations, individuals, and training that can impact team motivation and performance (Tannenbaum et al., 1993). Salas and colleagues (2007) reviewed and integrated over 50 models on team effectiveness; the

result was a comprehensive yet parsimonious framework of team effectiveness that can be used to tailor training.

Researchers and organizations have continued to benefit from developments in our knowledge of the training process and the factors that influence it. However, our knowledge is far from comprehensive. In our review of the literature, we noticed a heavy theoretical emphasis on training transfer. This is not a misplaced emphasis, for if transfer does not occur, then much of the purpose of training has been nullified. Despite the importance of transfer, it would be useful to see theoretical (and empirically grounded) universal models of the individual elements of training. These elements are discussed in the subsequent section.

## 2.1 Summary

Since Campell's (1971) review of the training literature, researchers have made great efforts toward solidifying the science of training. It is no longer a point of contention that training is atheoretical. Framework and models are more solid, and the field as a whole is much more empirical (Chen and Klimoski, 2007). While research is never complete, practioners can be confident that their efforts, when conducted in accordance with scientific findings, are founded on strong empirical evidence.

## 3 INSTRUCTIONAL SYSTEMS DEVELOPMENT MODEL

Our discussion of the design, delivery, transfer, and evaluation of training in this chapter is organized on the basis of a macrolevel systems approach. Specifically, we adopt the systems approach put forth by Goldstein (1993) in which four items serve as the basic foundation: (1) training design is iterative and hence feedback is continuously used to update and modify the training program; (2) complex interactions develop between training components (e.g., trainees, tools, instructional strategies); (3) a framework for reference to planning is provided; and (4) training systems are merely a small component of the overall organizational system and hence characteristics of the organization, task, and person should be considered throughout training design. Additionally, much of this chapter is guided by the instructional systems development (ISD) model (Branson, et al., 1975), which was established nearly four decades ago. Initially used in the development of U.S. military training programs, the ISD model continues to be used today and has been regarded as the most comprehensive training model available (Swezey and Llaneras, 1997). The model has also been the subject of criticism, however; thus we do not suggest that it is without flaws or superior to other models. Instead, we view it as a valuable framework for organizing the material we present in this chapter.

In the ISD model, occasionally referred to as the ADDIE model, training consists of five basic stages: analysis (A), design (D), development (D), implementation (I), and evaluation (E). Consistent with the previous review (Salas et al., 2006b), we also include a sixth step, namely transfer of training, as we continue to argue for its critical role in the training process. The process begins with the first phase, *training analysis*, in which the needs and goals of the organization are identified, and the overall plan for the design, delivery, and evaluation of the training is formulated. In the second phase, *training design*, learning objectives and performance measures are developed, and the progression of the training program is further mapped out. The training is fully developed in phase 3, *training development*, and weaknesses are identified and revised before the program is implemented. In the next phase, *training implementation*, final preparations are made (e.g., selecting a location where the training will be conducted), and the training is actually implemented. The training *evaluation phase* should follow, in which a multilevel approach is used to evaluate the effectiveness of the training. Finally, the *training transfer* phase should be implemented in order to determine the degree to which trained competencies are applied when the trainees return to the work environment. We utilize our knowledge of the science of training to describe each of these phases and form an integrated discussion of training as a whole.

While we adopt the ADDIE model of training and use it as the organizational framework for this review, other instructional design models exist (over 100; Chen, 2008). A few that bear mention are the rapid prototyping, R2D2, and 4C/ID models (Chen, 2008; Swaim, 2005; van Merriënboer and Kester, 2008). The rapid prototyping model is a form of ISD that developed in response to the breakneck pace of technological developments; the overall goal of this model is to utilize the key elements of ISD, but to do so much faster. This is accomplished by layering the different elements of instructional design. That is, even while the training designer is still analyzing training needs, he or she begins contructing and testing a prototype; when training objectives finally start to materialize, the training designer will still be developing and implementing trial runs of the training (Chen, 2008, Swaim, 2005). The "recursive, reflective, design, and development" model (R2D2; Chen, 2008) suggests a nonlinear approach to instructional design. While not as specific as the ADDIE model, it acknowledges a salient truth about training design: It never goes as planned. The R2D2 model of training design asserts that the process of reconsidering, rethinking, and revamping one's training is almost a neverending struggle throughout the training design and implementation; it is this amorphous, constantly evolving form of instructional design that delineates this from other theories of ISD (Chen, 2008). Finally, the 4C/ID (four components instructional design), discussed in the previous section, has implications for the development, design, and delivery of training systems (van Merriënboer and Kester, 2008). This holistic approach to training may be advantageous for trainers training for a complex set of tasks, as this model takes into account the complexity of the tasks, their interactions with each other, and the impact this may have on the learning process.

### 3.1 Summary

Though there are multiple models available in the literature, we argue for a systems approach and use the instructional design model to guide the organization of this chapter. Because no model is without flaws, the effective design, delivery, and evaluation of training may require a combination of several models.

## 4 TRAINING ANALYSIS

Before designing or implementing a training program, a training needs analysis is essential (Goldstein and Ford, 2002). Such an analysis includes where an organization needs training, what needs to be trained, and who needs the training (Goldstein, 1993). Training needs analysis will lead to (1) specifying learning objectives, (2) guiding training design and delivery, and (3) developing criterion. Needs assessment is vital in setting these training goals and determining the readiness of participants (Aguinis and Kraiger, 2009). But despite the foundational nature of training needs analysis, very little empirical analysis is available on its effectiveness, even at this juncture in the literature (Dierdorff and Surface, 2008; Tannenbaum and Yukl, 1992). Following is an explication of the three aspects of training analysis: organizational, job/task, and person.

### 4.1 Organizational Analysis

Organizational analysis is the first step in conducting training needs analysis. Various organizational aspects that may affect training delivery and/or transfer are considered through organizational analysis. This includes organizational climate/culture, norms, resources, constraints, support, et cetera (Festner and Gruber, 2008; Goldstein 1993). Another key element of organizational analysis is determining the "fit" of training objectives (see Section 5.1) with organizational objectives. For example, if an objective of training is to encourage appreciation for diversity, the organization must reflect that goal in day-to-day practice. A supportive organizational climate for transfer and application of trained KSAOs is vital for effective training; this concept is explored in further detail later (Bunch, 2007; Rouiller and Goldstein, 1993; Tracey et al., 1995). Considering that organizational factors can have a great impact on the implementability, continuity, and effectiveness of a training program, organizational analysis is a vital step in training needs analysis.

It has been nearly two decades since researchers began recognizing the importance of organizational analysis; this has led to several well-cited studies of the impact of the organization on training. Essentially, what has been found is that organizational climate (e.g., situational cues, consequences, support) is a strong predictor of training transfer (Lim and Morris, 2006; Rouiller and Goldstein, 1993; Tracey et al., 1995). For example, an organization implementing a sexual harassment training program that does not foster a climate of safety and openness will see little training effectiveness (Knapp and Kustis, 1996). But despite the clear importance of organizational factors on training transfer,

a recent meta-analysis by Arthur and colleagues (2003) showed inconsistent effects of organizational analysis on training effectiveness because there were *only four studies* that included this vital aspect of needs analysis.

### 4.2 Job/Task Analysis

After identifying organizational characteristics relevant to the intended training program, it is necessary to conduct a job/task analysis. The aim of this analysis is to identify characteristics of the actual task being trained for, so that the training program has specific, focused learning objectives (Goldstein, 1993). The first step is specifying the essential work functions of the job as well as requisite resources for job success. After outlining these generalities, specific tasks are identified. Furthermore, the contexts under which these tasks will be performed must be specified. Finally, task requirements and competencies (i.e., knowledge, skills, and attitudes) need to be defined. Often, this final step is the most difficult, because vague task requirements such as knowledge and attitudes are often difficult to observe in practice and thus are likely to be overlooked when designing training.

More complex tasks, however, may require an analysis of the cognitive demands (e.g., decision making, problem solving) of the tasks. These competencies are less observable and therefore require a specific cognitive task analysis to uncover them.

#### 4.2.1 Cognitive Task Analysis

Recent research has focused on trainees' acquisition and development of knowledge and how they come to understand processes and concepts (Zsambok and Klein, 1997; Schraagen et al., 2000). Additionally, research has acknowledged the importance of understanding subject matter experts' (SMEs') decision making in natural, complex settings (Gordon and Gill, 1997). A more targeted approach for identifying SME task cognitive processes is necessary, as SMEs' awareness of their skills tend to fade as they become more automated (Villachica and Stone, 2010). Cognitive task analysis (CTA) has emerged as the primary tool for understanding these processes (Salas and Klein, 2000). Various elicitation techniques (discussed subsequently) are used in CTA to specify cognitive processes involved in learning (trainees) as well as maximal performance (experts) (Villachica and Stone, 2010; Cooke, 1999; Klein and Militello, 2001).

It has been suggested that three criteria are essential to successful CTA (Klein and Militello, 2001). First, CTA must identify new information regarding trainees' patterns and strategies for learning and task success as well as other cognitive demands (e.g., cue patterns). This may be done through a variety of elicitation methods, such as structured and unstructured interviews, observing and coding of actual behaviors, or elicitation by critiquing. Elicitation by critiquing refers to having SMEs observe prerecorded scenarios and then critique the processes occurring in that recording (Miller et al., 2006). Second, these findings must be conveyed to training designers, who will incorporate them into the training design. The successful (read: impactful)

incorporation of CTA findings into training design is the final step of effective CTA. A potential prerequisite has been suggested for successful CTA: accurately identifying SMEs; this is a more complex undertaking than one might initially think (see Hoffman and Lintern, 2006). The steps for conducting a cognitive task analysis are summarized in Table 1.

### 4.3 Person Analysis

The final stage of training needs analysis is person analysis. Person analysis encompasses who needs training,

what they need to be trained on, and how effective training will be for individuals (Tannenbaum and Yukl, 1992; Goldstein, 1993). The foundation of person analysis is that not everyone needs the same training, and not everyone responds similarly to all training. Different job domains within organizations require different training, as do individuals with differing levels of expertise (Feldman, 1988). Even employees within the same job domain (i.e., management) operating at different levels tend to need training and view training differently due to varying job demands (Lim and Morris, 2006; Ford

**Table 1  Steps in Conducting Cognitive Task Analysis**

| Step | Guidelines |
|---|---|
| 1. Select experts. | • Consider how many SMEs would be appropriate.<br>• Select SMEs who have experience with domain.<br>• Select SMEs who have experience with task. |
| 2. Develop scenarios based on task analysis. | • Develop scenarios that are task relevant with problem statements.<br>• Pretest scenarios to determine if they are complete. |
| 3. Choose a knowledge elicitation method. | • Determine the information you are trying to get at. |
|    • Interviews | • Ask SMEs about cognitive processes needed to complete task scenarios. |
|    • Verbal protocols | • Require SMEs to think out loud as they complete task scenarios. |
|    • Observations | • Observe SMEs performing tasks. |
|    • Conceptual methods | • Develop inferences based on SME input and relatedness judgments. |
|    • Critiquing | • Have SMEs outline cognitive needs based on their observations of prerecorded scenarios. |
| 4. Implement chosen knowledge elicitation method. | • Decide how many sessions to be recorded.<br>• Obtain consent and provide task scenario to SMEs. |
|    • Interviews | • Provide each scenario to each SME.<br>• Ask SMEs relevant questions:<br>  What rules/strategies would you use to complete scenarios?<br>  What knowledge and cognitive skills would you use to complete scenarios?<br>  If A or B happens, what would they do?<br>• Keep a record of SME responses: use video, audio, pen and paper, etc. |
|    • Verbal protocols | • Provide each scenario to each SME.<br>• Require SMEs to think out loud as they complete task scenarios.<br>• Keep a record of SME responses: use video, audio, pen and paper, etc. |
|    • Observations | • Provide each scenario to each SME.<br>• Be as unobtrusive as possible, but do not be afraid to ask for clarification when necessary.<br>• Keep a record of SME responses: use video, audio, pen and paper, etc. |
|    • Conceptual methods | • Provide each scenario to each SME.<br>• Present pairs of tasks to experts.<br>• Ask SMEs for relatedness judgments regarding task pairs. |
|    • Critiquing | • Provide each scenario to each SME.<br>• Have SMEs critique performance observed in the scenario<br>• Ask SMEs to identify cognitive processes at play in scenarios |
| 5. Organize and analyze data. | • Keep a record of similarities between SMEs.<br>• Interview additional experts if questions arise from data.<br>• Identify the rules and strategies applied to the scenario.<br>• Identify knowledge and cognitive skills required.<br>• Generate a list of task requirements.<br>• Verify list with additional SMEs. |

*Source:* Adapted from Salas et al. (2006b)

and Noe, 1987). Person analysis identifies individuals' possession of the requisite competencies outlined in task analysis. As previously noted, knowledge and attitudes are also frequently considered competencies to be included in training needs analysis, and person analysis places emphases on these. Individual characteristics such as personality, self-efficacy, goal orientation, and prior training experience have all been shown to impact training effectiveness and should therefore be considered in training needs analysis (Rowold, 2007; Chiaburu and Lindsay, 2008; Roberson et al., 2009; Velada et al., 2007; Cheramie and Simmering, 2010).

One aspect of the person that often has bearing on what kind of training is used is individual learning styles. The concept of learning styles refers to the notion that individuals prefer specific instructional methods (e.g., visual, auditory, experiential) and that, when instructional strategies match learning styles, individuals learn significantly better. While this is by no means a new hypothesis, a recent review of the concept provides insights relevant to person analysis. In their review of the literature, Pashler et al. (2008) found that, as of late, research has not supported the learning styles hypothesis. However, they note that not all hypothesized learning styles have been studied, so the theory cannot be discounted entirely. The overall suggestion stemming from this review is that training designers need not be overly concerned with tailoring instructional strategies to learning styles, but simply need to use the instructional strategy that best fits the KSAOs being trained.

### 4.4 Summary

For training to be effective, training needs analysis is a necessity. If trainees do not meet the requirements for training (e.g., possess necessary competencies and attitudes), if training is essentially irrelevant to the actual job, or if aspects of the organization (e.g., culture, support) are not conducive to training, training will fail. Our suggestion: Thoroughly analyze training needs before designing any training system.

## 5  TRAINING DESIGN

Training design is the natural outcome of training needs analysis and is the next step in the ISD framework. Analysis-driven training design ensures that training is systematic and provides structure to the training program. Several things must be taken into account when designing training: development of training objectives, external factors relevant to the training program (i.e. individual/organizational characteristics and resources), selection of training strategies and methods, and developing specific program content.

### 5.1 Training Objectives

Training and learning objectives are developed in accordance with the training needs analysis. Objectives should be specific, measurable, and task relevant so that learning and performance can be evaluated posttraining. There are three components to training objectives: *performance*, *conditions*, and *standards* (Buckley and

Caple, 2007; Goldstein, 1993). *Performance* refers to both the end goal of training (terminal objective) and the requisite process behaviors (enabling and session objectives) to reach the end goal. Performance objectives can be laid out in a hierarchy such that session objectives (mundane behaviors) aggregate to enabling objectives, which are the major components of the terminal objective, or the end goal of training. *Conditions* also must be specified as to when and where these behaviors must be exhibited. *Standards* is the final component of training objectives; this refers to specifying what will be considered acceptable performance levels of the various objectives. Clearly defined objectives are able to effectively guide the training designers' choice of instructional strategy (or strategies). These strategies are selected according to their ability to promote objective-based behaviors and competencies. See Table 2 for guidance on developing training objectives.

### 5.2 Individual Characteristics

An important aspect of any training program is the individuals that receive it. Accordingly, the individual characteristics that participants bring to the training program, such as cognitive ability, self-efficacy, goal orientation, and motivation, must be considered when designing any training program. Each of these characteristics is discussed in the following.

#### 5.2.1 Cognitive Ability

Research has shown cognitive ability (i.e., $g$, or general mental ability) has clear and strong effects on the outcomes of training. Cognitive ability positively influences on-the-job knowledge acquisition (see Ree et al., 1995; Colquitt et al., 2000) and generally impacts trainees' ability to learn, retain, and transfer training material (Burke and Hutchins, 2007). Overall, individuals higher in cognitive ability are more likely to achieve training success on all fronts.

#### 5.2.2 Self-Efficacy

Self-efficacy, or the individual's belief in personal ability, is another individual characteristic that has exhibited strong effects on reactions to training (Mathieu et al., 1992), motivation within training (Chiaburu and Lindsay, 2008; Quinones, 1995), training performance (Tziner et al., 2007; Ford et al., 1997; Stevens and Gist, 1997), transfer of training (Velada et al., 2007), and application of training technology (Christoph et al., 1998). Self-efficacy has also been shown to mediate several important training relationships, such as between conscientiousness and learning (Martocchio and Judge, 1997) and training and adjustment (Saks, 1995), as well as many other individual characteristics and transfer, both analogical and adaptive (Bell and Kozlowski, 2008).

#### 5.2.3 Goal Orientation

Goal orientation, defined as the mental framework that determines behavior in different goal-oriented environments, has been heavily researched as to its

**Table 2  Steps in Developing Training Objectives**

| Step | Guidelines |
|---|---|
| 1. Review existing documents to determine job tasks and competencies required. | Examine your sources:<br>• Performance standards for the organization<br>• Essential task lists<br>• Past training objectives<br>• SMEs and instructors to mine their previous experiences |
| 2. Translate identified competencies into training objectives. | Include objectives that:<br>• Specify targeted behaviors<br>  • Use ''action'' verbs (e.g., ''provide,'' ''prepare,'' ''locate,'' and ''decide'')<br>  • Outline specific behavior(s) that demonstrate the appropriate skill or knowledge<br>  • Can be easily understood<br>• Clearly outline the conditions under which skills and behaviors should be seen<br>• Specify standards to which they will be held when behaviors or skills are performed or demonstrated<br>  • Make sure that standards are realistic<br>  • Make sure that standards are clear.<br>  • Make sure that standards are complete, accurate, timely, and performance rated |
| 3. Organize training objectives. | Make sure to categorize:<br>• General objectives that specify the end state that trainees should attain/strive for<br>• Specific objectives that identify the tasks that trainees must perform to meet the general objectives |
| 4. Implement training objectives. | Use training objectives to:<br>• Design exercise training events (e.g., scenarios)<br>  • Use events as opportunities to evaluate how well trainees exhibit training objectives<br>• Develop performance measurement tools (e.g., checklists)<br>• Brief trainees on training event |

*Source:* Originally published in Salas et al. (2006b).

impacts on learning and transfer (Kozlowski and Bell, 2006; Phillips and Gully, 1997; Ford et al., 1992). Early theorizing on the issue dichotomized goal orientation between either mastery or performance orientations (see Dweck and Leggett, 1988). Mastery orientation has been shown to impact knowledge-based learning outcomes (Ford et al., 1997), self-efficacy (Phillips and Gully, 1997), motivation and satisfaction (Orvis et al., 2009), as well as overall training effectiveness (Orvis et al., 2009; Klein et al., 2006; Tziner et al., 2007). On the other hand, performance orientation has exhibited many negative effects on training (Orvis et al., 2009; Tziner et al., 2007). Debate exists as to the nature of goal orientation, however. Research has explored whether goal orientation is a state or a trait (Stevens and Gist, 1997), a multidimensional construct (Elliot and Church, 1997; Vandewalle, 1997), or even mutually exclusive (Buttom et al., 1996). Regarding this last question, some researchers have encouraged another level of goal orientation, approach–avoid (see Elliot and McGregor, 2001). While studies on the simple mastery–performance dichotomy are much more plentiful, the mastery–approach orientation has been shown to be the learning orientation most strongly associated with positive training attitudes (Narayan and Steele-Johnson, 2007).

### 5.2.4 Motivation

Trainee motivation can be defined as the direction, effort, intensity, and persistence that individuals exert towards training-relevant behaviors and learning before, during, and after training (Naylor et al., 1980, as cited in Goldstein, 1993). Learning-oriented motivation has been shown to affect acquisition and retention of knowledge as well as willingness to participate (Tziner et al., 2007; Klein et al., 2006; Martocchio and Webster, 1992; Mathieu et al., 1992; Tannenbaum and Yukl, 1992; Quinones, 1995). Motivational levels can be impacted by individual (e.g., self-efficacy) and organizational (e.g., culture) characteristics as well as characteristics of the training itself (i.e., some training may be more interesting/motivating than others). Self-efficacy toward training and instrumentality of training have both been shown to positively impact training effectiveness (Rowold, 2007; Roberson et al., 2009). Training instrumentality, or the expected usefulness of training content, tends to predict motivation to transfer (Chiaburu and Lindsay, 2008; Noe, 1986); pretraining motivation has similarly been shown to predict positively training effectiveness and trainee reactions (Burke and Hutchins, 2007; Tannenbaum et al., 1991; Mathieu et al., 1992).

While the literature on training motivation has been criticized as lacking in conceptual precision and specificity (Salas and Cannon-Bowers, 2001), strides have been made toward identifying the underlying processes of trainee motivation. Colquitt and colleagues (2000) greatly bolstered this field with their meta-analysis on the topic which revealed that motivation to learn is impacted by individual (e.g., self-efficacy, cognitive ability) and situational (e.g., organizational climate, supervisory support) characteristics. These findings have

been further replicated in more recent empirical studies (Major et al., 2006; Nijman et al., 2006; Scaduto et al., 2008) as well as meta-analyses (Sitzmann et al., 2008). Burke and Hutchins (2007) note that motivation to transfer is impacted by motivation to learn, self-efficacy, utility reactions, and organizational climate. Furthermore, they note inconsistencies in the literature as to whether intrinsic or extrinsic motivation is more effective in encouraging transfer. The multifaceted nature of motivation thus demands attention when designing training.

### 5.3 Organizational Characteristics

While individual characteristics do indeed affect training outcomes, organizational characteristics (i.e., the organization to which training is relevant) also play a role in determining training outcomes. These may include organizational culture, policies and procedures, miscellaneous situational influences (e.g., improper equipment), and prepractice conditions (see Salas et al., 1995). These organizational characteristics must be accounted for when designing training.

#### 5.3.1 Organizational Culture

Since the 1980s, when the term *organizational culture* began to be discussed in the literature, research has suggested that organizational culture is vital to an organization's success (Guldenmund, 2000; Glendon and Stanton, 2000). Organizational culture has been defined as "a pattern of shared basic assumptions that the group learned as it solved its problems of external adaptation and internal integration" (Schein, 1992, p. 12). These assumptions and other aggregate behaviors and social norms must then be inculcated to trainees, such that employees will think and respond to situations similarly and harmoniously (Schein, 1992). Organizational leaders play a vital role in transmitting preexisting organizational cultures to new employees through the socialization process (Burke, 1997). For example, supervisory support of training has been shown to foster an organizational culture supportive of training and learning, which in turn positively impacts training outcomes (Nijman et al., 2006).

#### 5.3.2 Policies and Procedures

Out of an organization's policies and procedures arise its organizational culture. Broad requirements and expectations (e.g., job performance, interpersonal relations) comprise an organization's policies (Degani and Wiener, 1997), while more specific guidelines as to how to follow the policies comprise an organization's procedures. For example, if a company has a policy that emphasizes employees' punctuality, management may implement procedures to assist/ensure this policy is met (e.g., time card, consequences for tardiness). Training programs can be designed to inform trainees of these policies and procedures in such a way that they will more effectively perform them on the job. There can be issues, however, when implicit social norms are contraindicative of training goals (e.g., Hofmann and Stetzer, 1996). Continuing the punctuality example above, if there are social situations that allow (or rather, do not disallow) employees

to have excessive flexibility with their punctuality (e.g., having other employees punch time cards), the written policies, procedures, and training will be less effective. This is a real problem with real consequences that has been dramatically evinced within the oil industry (Wright, as cited in Hofmann et al., 1995). Unfortunately, organizations often do not engage in behaviors supportive of training before or after training when targeted behaviors are most likely to subside (Saks and Belcourt, 2006). If policies and procedures are to be enacted throughout an organization, policies and procedures must be implemented within management that support the development of lower level policies and procedures.

#### 5.3.3 Situational Influences

Several aspects of the training situation have been shown to have significant effects on trainees' motivation to learn as well as transfer of knowledge from training to the job: framing of training, work environment, and previous training experience. Framing of training typically refers to whether attendance is voluntary or mandatory; research has shown trainees respond more positively to voluntary framing (Baldwin and Magjuka, 1997). Training can also be framed from remedial/advanced or mastery/performance (recall the discussion on learning goal orientation). Using these frames can have important effects on reactions to training (Quinones, 1995, 1997; Kozlowski and Bell, 2006). Even doing something as simple as labeling training as an "opportunity" can have positive effects (Martocchio, 1992). The work environment and perceptions thereof can also have an effect on motivation and training transfer (e.g., Goldstein, 1993). Work environment can refer to organizational culture and supervisory support (as previously discussed); it can also be more tangible, such as lack of materials/information (e.g., Peters et al., 1985) or even lack of time to apply learning (Festner and Gruber, 2008; Lohman, 2009). Lastly, prior training experiences, especially negative ones, have been shown to negatively affect further training endeavors (Smith-Jentsch et al., 1996aa). These conditions must all be taken into account when designing a training program.

#### 5.3.4 Prepractice Conditions

Certain conditions have been shown to better prepare trainees for practice during training; these are termed prepractice conditions. Research has well evinced the positive impact practice has on skill acquisition, but not all practice is the same. However, due to the complex nature of the skill acquisition process, simple task exposure or repetition is not enough (Schmidt and Bjork, 1992; Shute and Gawlick, 1995; Eherenstein et al., 1997). Cannon-Bowers and colleagues (1998) provide a good review of conditions antecedent to enhanced utility and effectiveness of practice. This review suggests that prepractice interventions, such as preparatory information, advanced organizers, or metacognitive strategies, can help prepare trainees for and encourage learning within training. For example, Frey and colleagues (2007, as cited in Orvis et al., 2008) found that providing prepractice training on novel

instructional media increased performance and learning, especially for novel users.

## 5.4 Practice Opportunities

A vital aspect of any training program is the practice opportunities offered to trainees during training. Research has shown that practice under conditions (either simulated or real) that differ from the end-goal task will improve on-the-job performance by developing meaningful contexts and knowledge structures (i.e., mental models) (Satish and Streufert, 2002). Scripted practice scenarios ensure that the necessary competencies are being practiced and will allow for easier and better performance assessment. Beyond simply increasing performance, practice should also improve overall task-relevant learning. In a 2006 meta-analysis of training literature, Sitzmann and colleagues found that Web-based instruction led to more learning than classroom instruction, not because of the media itself but because it allowed learners more control and to *practice* the material at their own pace. That more practice opportunities lead to more learning is a finding replicated in other studies as well (Festner and Gruber, 2008; Goettl et al., 1996). Research has also been done on the scheduling of practice opportunities as well as introducing variations in practice difficulty (Schmidt and Bjork, 1992; Ghodsian et al., 1997). These studies have shown that varying the order of tasks during practice, providing less feedback (both in quality and quantity), and introducing alterations in the specifics of the tasks being practiced all led to enhanced retention and generalization, despite exhibiting initial decreases in task performance. This suggests that varying practice opportunities in such a fashion actually leads to deeper learning. Shute and Gawlick (1995) confirmed these findings for computer-based training. One thing to note: When the training medium is unfamiliar to the trainee (e.g., video games), introducing difficulty in practice will be less beneficial than for experienced users (Orvis et al., 2008), as they expend cognitive resources on learning the medium rather than the task.

## 5.5 Feedback

Constructive and timely feedback is important to the success of any training program. If not for feedback, trainees would have no metric by which to determine where improvements are needed or if performance is sufficient (Cannon-Bowers and Salas, 1997). Research has consistently shown that feedback leads to increases in learning and performance (Burke and Hutchins, 2007). However, effective feedback must meet three criteria. First, feedback should be task/training performance based but not critical of the person. Second, feedback should provide information and strategies on how to improve learning strategies so that performance expectations are met. Finally, feedback must be seen as meaningful at all applicable levels (i.e., individual and/or team). Feedback strategies may also vary depending on task complexity; "scaffolding" is a technique that involves gradually *reducing* the amount of feedback provided so as to encourage self-monitoring of errors (van Merrienboer et al., 2006). However, such techniques are

still in need of further research as to their effectiveness and generalizability (Burke and Hutchins, 2007).

## 5.6 Instructional Strategies

A key element of training design is the instructional strategy selected. Characteristics of the trainee and the organization must be considered so as to select the most appropriate strategy. There exist a myriad of instructional strategies that may be effective for training both individuals and teams; Table 3 summarizes many of these strategies.

Four basic guidelines should guide training designers seeking to develop effective training: (1) Information or concepts to be learned must be presented, (2) necessary KSAOs to be learned/acquired must be demonstrated, (3) opportunities for practices should be provided, and (4) feedback during and after training must be given to trainees. As is evident from Table 3, much research has been done toward investigating training strategies, but no single method is totally effective at meeting all training needs. Accordingly, research continues on how to present targeted information to trainees, based on factors such as organizational resources and training needs. Current research, then, seeks to develop and test validated, user-friendly, interesting, and interactive training tools with high return on investment (ROI) (e.g., Bretz and Thompsett, 1992; Baker et al., 1993; Steele-Johnson and Hyde, 1997).

As organizations continue to move into the future, several issues affecting training and training strategies will continue to increase in saliency: (1) reliance on workplace teams, (2) advances in technology, and (3) globalization. Therefore, the instructional strategies discussed here are organized accordingly. However, future training strategies cannot simply acknowledge and incorporate these factors while ignoring three universal training issues: (1) adaptability, (2) feedback, and (3) interactivity. *Adaptability* refers to trainees' acceptance of change and adoption of flexible knowledge structures (i.e., mental models); the breakneck advances in technology demand adaptability of today's employee. *Feedback* simply refers to the need for training programs to provide constructive information regarding performance to trainees; this allows them to adjust their efforts to better their performance. Training programs should increasingly incorporate *interactivity*; while this element has been shown to have some positive effects, it should not be applied blindly, as learner control inherent in interactive programs has been shown to have inconsistent effects (Aguinis & Kraiger, 2009). Recent reports have exhibited the upward trend in technology use in training—approximately 26% of learning hours in 2004 were technology based, and this increased to 32% as recently as 2007 (Paradise, 2008), but there clearly are more arenas where interactive training programs might be utilized.

### 5.6.1 Teams

Over the past half century, organizational theory and business practices have changed a great deal. A major facet of these changes has been the upwards trend of workplace teams and their use in health care,

**Table 3  Instructional Strategies**

| Strategy | Definition | References |
|---|---|---|
| Technology-based strategies | | |
| Simulation-based training and games | Provides practice opportunities through technology. Has the potential to create realistic scenarios by simulating terrain, events, and social interactions; has been applied to military, business, medical, cross-cultural, and research settings. Varies regarding fidelity, immersion, and cost. | Tannenbaum and Yukl (1992), Marks (2000), Bell et al. (2008) |
| Behavior modeling training | Presents the trainee with examples (positive and negative) of targeted behaviors. Can be done in a variety of settings but is often done electronically. Essentially a combination of simulation and role playing and varies as to the degree of interactivity. | Taylor et al. (2005) |
| Distance learning | Allows instructors and students physically or synchronously separated to interact. Utilizes technologies such as the Internet, CD/DVD-ROM, videoconferencing, and text messaging. Includes both electronic and nonelectronic forms of training. | Moe and Blodget (2000), Orvis et al. (2009) |
| E-learning | Same concept as distance learning but is strictly electronic and generally more interactive. Uses the Internet, text messaging, virtual classrooms, online collaboration, and a host of other technologies to quickly connect learner and instructor. Time-pressured employees are typically ideal candidates for this training. | Kaplan-Leiserson (2002) |
| Learner control | Allows trainees to exercise personal control over certain aspects of the training (e.g., content, delivery structure, pacing). A key component of many distance, e-learning, and other technology-based instructional strategies. | Wydra (1980), Brown and Ford (2002), Sitzmann et al. (2006) |
| Scenario-based training | Similar to simulation-based training, in that it provides complex and realistic environments. It is more targeted, however, as it embeds task-relevant events with behavioral triggers into the program. The program then monitors performance and provides feedback on the task and processes within the scenarios. | Fowlkes et al. (1998), Oser et al. (1999a,b), Salas et al. (2006) |
| Collaborative learning | Utilizes technology to enable groups to train together. This may happen with collocated or separated groups. Emphasizes group interaction and deemphasizes tasks. | Arthur et al. (1996, 1997), Marks et al. (2005) |
| Error training | Allows, encourages, induces, or guides trainees to make errors within the program. Trainees are shown the consequences of failure and provided with feedback. Especially necessary in situations when posttraining errors are likely or in highly dynamic and complex training areas. | Dormann and Frese (1994), Ivancic and Hesketh (1995), Keith and Frese (2008) |
| Stress exposure training | Informs trainees as to the potential stressors inherent in the targeted task as well as the relationship between stressors, trainee affect, and performance. Trainees also receive information on coping strategies. Training may also incorporate graduated exposure to actual stressors to desensitize trainees to potential stressors. | Johnston and Cannon-Bowers (1996), Driskell and Johnston, (1998), Driskell et al. (2008) |
| On-the-job training | Training occurs in the same environment in which actual task behavior will eventually be performed. Experts instruct novices, who then practice relevant tasks under supervision of the expert. Includes both apprenticeship and mentoring models. | Goldstein (1993), Ford et al. (1997), Munro (2009) |
| Team-based strategies | | |
| Team coordination training | Provides opportunities for teams to practice workload distribution, implicit and explicit communication, backing up behaviors, interpersonal relations, with the goal being maximal team coordination. This is becoming increasingly important as teams are on the rise even as face-to-face interactions are declining. | Bowers et al. (1998), Entin and Serfaty (1999), Serfaty et al. (1998) |

**Table 3 (continued)**

| Strategy | Definition | References |
|---|---|---|
| Cross-training | Rotates team members through the tasking of other team members. The goal is to provide team members with a better understanding of role requirements and responsibilities and to coordinate workload more effectively. Goal is improved shared mental models and understanding of technology usage across team members. A recent meta-analysis showed this strategy to be essentially ineffective. | Volpe et al. (1996), Salas et al. (1997a, 2007) |
| Team self-correction training | Fosters awareness of team processes and effectiveness so that team members can evaluate and correct their behaviors in the future. This is not only personal awareness but also awareness of the behaviors of other team members. Instructs teams to provide constructive feedback; may help mitigate errors due to miscommunications that naturally occur when adopting new technologies. | Blickensderfer et al. (1997), Smith-Jentsch et al. (1998), Salas et al. (2007) |
| Distributed team training | Allows physically and synchronously separated teams to develop competencies that optimize teamwork. These strategies help team members adjust their interactions to the complexities of separation, technology, and a plethora of other logistical issues. | Townsend et al. (1996), Carroll (1999) |
| Internationalization-based strategies | | |
| Individual-level strategies | Multicultural training was initially centered on either didactic (information-giving) or experiential instructional strategies. Cultural awareness and attribution training have increased in popularity as well for multicultural training. | Deshpande and Viswesvaran (1992), Kealey and Protheroe (1996) |
| Attribution training | Instructs trainees in various strategies that allow them to see the source of behavior (i.e., make attributions) similarly as individuals from a given culture. This also provides a better understanding and appreciation for other cultures. | Befus (1988), Bhawuk (2001), Littrell and Salas (2005) |
| Cultural awareness training | Emphasizes understanding the personal culture of the trainee, along with the various biases, norms, and thought patterns involved in that culture. Assumes that an awareness of one's own culture leads to a greater appreciation for and understanding of other cultures. | Bennett (1986), Befus (1988), Collins and Pieterse (2007), Thomas and Cohn (2006) |
| Didactic training | Provides trainees with various culturally relevant facts such as living and working conditions, cultural dimensions, values, logistics of travel, shopping, and attire and even food. Geographic, political, economic, and social structure information is also conveyed. | Kealey and Protheroe (1996), Morris and Robie (2001), Sanchez-Burks et al. (2007) |
| Experiential training | Emphasizes experiencing the aspects and consequences of cultural differences in various scenarios. Often occurs in the form of simulations but can even include face-to-face exposure to the targeted culture or role-playing exercises. Not only improves trainees' intercultural competence but also can serve a purpose similar to attribution training. | Kealey and Protheroe (1996), Morris and Robie (2001), Fowler and Pusch (2010) |
| Team-level strategies | Multicultural team training strategies train teams of culturally diverse individuals to optimize their performance. Five domains typically characterize multicultural team training programs: (1) enhancing specific aspects of performance through improvement of general team characteristics, (2) using a traditional team performance framework, (3) applying specific training tools and feedback, (4) utilizing a multimethod training method, and (5) training in a limited time frame. | Salas and Cannon-Bowers (2001) |
| Team leader training | Trains leaders on two domains of multicultural team leadership: (1) leadership and (2) culture. Often these are taught asynchronously, but some training programs have attempted to train leaders on both of these simultaneously. | Kozlowski et al. (1996), Thomas (1999), Burke et al. (2005) |

**Table 3** (*continued*)

| Strategy | Definition | References |
|---|---|---|
| Team building | Incorporates team members into organizational- or team-level change development and implementation. Forces team members to interact strategically. Emphasizes one of four team-building goals: goal setting, interpersonal relationships, problem solving, and role clarification. | Dyer (1977), Beer (1980), Buller (1986), Salas et al. (1999), Shay and Tracey (2009) |
| Role playing | Requires trainees to interact with other team members through the use of scripted scenarios. Progression through the roles can make team members aware of (1) their own culture (i.e., enculturation) or (2) other cultures (i.e., acculturation). Role playing can also support both of these goals when trainees experience multiple roles. | Bennett (1986), Roosa et al. (2002) |

*Source:* Adapted from Salas et al. (2006b).

government, manufacturing, and the military (e.g., Salas et al., 2008; Tannenbaum and Yukl, 1992; Guzzo and Dickson, 1996). Increasing workplace complexity has driven the need for teams (Salas et al., 2008), and advancements in technology, geopolitical stability, and research have enabled organizations to meet this need on an international level. This trending toward teams and organizational adaptability has leveled many traditional hierarchical structures (Kozlowski and Bell, 2002; Zaccaro and Baker, 2003). The vast majority of organizations utilize some form of team structure (Banker et al., 1996); similarly, in a 2001 survey by Fiore and colleagues, 80% of surveyed workers reported being members of at least one team. The generally held philosophy among organizations is that teams are the answer to many workplace problems; thus, as organizational life becomes increasingly complex, teams are implemented more readily.

This practical trending toward teams has led to a significant research emphasis on teams and team training (Salas et al., 2008; Salas and Cannon-Bowers, 2001). One of the major drivers of team training research has been in the commercial and military aviation communities (e.g., Salas et al., 1995). Crew resource management (CRM; Shuffler et al., 2010; Wiener et al., 1993) is specifically aviation relevant; other strategies such as cross-training and team self-correction training have also developed, validated in other organizational settings, and been widely discussed in the literature. While an in-depth discussion of these strategies would be essentially redundant, a summary of many team training strategies and additional resources has already been provided in Table 3. For a more exhaustive summary of team training strategies, we encourage the reader to explore other influential pieces in the literature (see Salas and Cannon-Bowers, 2001; Wilson et al., 2005; Salas et al., 2007, 2008). In addition to some of the more common strategies, team training strategies will increasingly be impacted by technology as well as globalization. These two concepts are explored at length in the following two sections.

### 5.6.2 Technology

As the strength and availability of technology increase at a breakneck pace, it is no surprise that training designers

have increasingly incorporated technology into their programs. However, technology-based instructional strategies currently only comprise little more than 30% of total practices (Paradise, 2008). With the recent and ongoing explosion of technological advancement in recent years, organizations must address not only incorporating technology into their training programs but also training employees to effectively utilize the new technologies. These issues, however, must not prevent organizations from adopting new and beneficial technologies. At one time, using "cutting-edge" technologies such as e-mail, text messaging, and videoconferencing seemed cumbersome and unnecessary to some. Technologies such as these are now considered the norm; we accept and expect them.

Recent surges in technology have allowed ever-increasing degrees of integration between technology (e.g., computer and Web based) and training (Goldstein and Ford, 2002; Rivera and Paradise, 2006). One of the alluring potentialities of intelligent (i.e., technologically based) tutoring systems is that it may reduce or eliminate the need for human instructors, especially given certain learning tasks. As early as 1995, Anderson and colleagues proposed that intelligent software could be programmed to monitor, assess, diagnose, and remediate performance for several tasks. More recently, it was shown that technology-driven tutoring software was superior to traditional instructional strategies when trainees were allowed time for practice because it provided opportunities for discovery (Brunstein et al., 2009). Learner control is a major component, and advantage, of many technology-based training programs. Allowing trainees to have control over certain elements such as training method, time for practice, and timing of feedback (e.g., Milheim and Martin, 1991) has been shown to have positive effects on trainee attitudes and motivation (e.g., Morrison et al., 1992) as well as learning and performance (Schmidt and Ford, 2003). In fact, in a recent meta-analysis, Sitzmann and colleagues showed that it was this element of control, and not the training media itself, that caused significant increases in learning (Sitzmann et al., 2006). Following is a brief summary of some of these technological instructional strategies as well as techniques to encourage and facilitate adoption of these new methods. The

technology of training, while still under much research, is an increasingly salient phenomenon. Organizations and training designers alike would do well to embrace it, given its considerable ability to improve upon the effectiveness and cost-efficiency of more traditional training methods.

***Simulation-Based Training and Games*** By far, simulation and game-based training have revolutionized the field of training, especially aviation and military training. In the late 1960s, theories regarding simulation-based training was new and unique (Ruben, 1999). At that point, training and learning were thought to occur primarily in a classroom setting, driven by books, articles, and lectures. However, technology-assisted training strategies are now readily accepted by nearly all and are often preferred by some trainees. Much of this has to do with the ability to actually practice targeted KSAOs, something which is often much more difficult in a classroom setting. Furthermore, the flexibility of many simulation programs means KSAOs can be practiced in a wide variety of settings and situations; this increases the likelihood of training transfer and generalization (Richman et al., 1995; Salas et al., 2006; Sitzmann et al., 2006). Accordingly, we are seeing, with increasing frequency, the use of simulations and computer games for instruction, practice, and feedback.

Training through simulation continues to be a popular method in business, education, and the military (Jacobs and Dempsey, 1993). The military is the main investor in simulation studies, having contributed $150 million to $250 million each year since the 1960s towards the field (Fletcher, 2009). Research has shown that simulation-based training strategies are effective, but the literature is unclear as to *why* it is effective. Several studies have offered preliminary data (e.g., Ortiz, 1994; Bell and Waag, 1998; Jentsch and Bowers, 1998), but explanatory models are yet to be widely accepted. Due to this paucity in the literature, it may be premature to say that simulation (in and of itself) leads to learning. Furthermore, a major confound exists in current research in that much of the training research evaluates trainee reactions while ignoring actual performance (see Salas et al., 1998). Some research, however, has suggested that the major advantage simulation-based training and other technology-based training methods have over traditional training strategies is the control they offer trainees, which has been shown to have positive effects on reactions, motivation, and performance (Orvis et al., 2009; Sitzmann et al., 2006). Other advantages are decreased learning time, complex but controllable practice environment, and the ability to prepare trainees for critical but rare events (Salas et al., 2009). However, further research is still required to provide a more thorough explanatory framework as to the effectiveness of simulations, even as the method becomes more and more ubiquitous.

As previously suggested, unique and relevant practice opportunities are a major advantage of simulation-based training. Structuring training around relevant scenarios is a vital and effective instructional strategy for individuals and teams operating in complex, time-oriented environments. Simulations can train a wide variety of domain-relevant KSAOs. Flight simulation has consistently been the most common application of simulation-based training and has driven much of the research in training technology. Adaptive decision making (e.g., Gillan, 2003), discrimination, performance (Aiba et al., 2002), response time (Harris and Khan, 2003), performance under workload (Wickens et al., 2002), and team issues (Prince and Jentsch, 2001) have all benefitted from research grounded in flight simulators. Similarly, driving simulators have begun to leave the domain of simple evaluation and have become popular methods of all forms of driver training (e.g., Fisher et al., 2002; Roenker et al., 2003). Medicine has also adopted simulation-based training (e.g., the METI doll; METI, 2010) to train both individual- and team-based skills. Additionally, multicultural training has embraced simulation-based training to improve the effectiveness of cross-cultural interactions (see "Individual Cultural training Strategies" in Section 5.6.3). Second Life™, a free, user-driven computer game, has been adapted to train for cultural awareness and competence, for example (Fowler and Pusch, 2010). Other arenas where simulation-based training has shown great promise have been health care (e.g., Rosen et al., 2008; Steadman et al., 2006), transportation (e.g., Tichon, 2007a), and the military (Salas et al., 2006). For example, presenting train conductors with complex, life-threatening scenarios (e.g., workers on the track), and training them accordingly, will foster in trainees an ability to make complex decisions quickly when necessary (Tichon, 2007a).

Simulation-based training varies greatly with regard to cost, fidelity, and functionality. Early simulators were typically extremely low in physical fidelity (i.e., realism), but with recent advances in technology, simulators and virtual environments now have the ability to emulate environmental characteristics such as terrain, equipment failures, motion, vibration, and much more. While simulations high in physical fidelity may better engage trainees in training and may also help in preparing for the details of complex situations (Bell et al., 2008), systems low in physical fidelity can often just as effectively represent targeted KSAOs (e.g., Jentsch and Bowers, 1998). Furthermore, these low-fidelity systems can still have positive effects on immersion, engagement, motivation, and learning over lecture and/or text-based instructional strategies, especially when the system has some sort of game element (i.e., interactivity, competition) (Bell et al., 2008, Ricci et al., 1995).

Despite the increasing availability of high-fidelity simulations, the trend recently has been toward lower fidelity, computer-based simulation systems, even when training complex skills. Beyond cost effectiveness, another practical rationale for this is that simulators low in physical fidelity can actually excel in psychological fidelity (i.e., representation of constructs and processes implicit in performance). These training systems then should actually result in more skills transfer and behavioral generalization after training (e.g., Bell et al., 2008; Gopher et al., 1994). Driven by such thinking, researchers have examined simple off-the-shelf computer games for training complex skills;

studies have shown that these low-fidelity simulations can indeed improve performance in highly complex situations (e.g., Fong, 2006; Gopher et al., 1994; Goettl et al., 1996; Jentsch and Bowers, 1998). It is important to note that these simulations were programmed around a skill-oriented task analysis; task analysis is vital to ensure the psychological fidelity of simulation training systems.

While simulation-based training has increased in prevalence consistently throughout recent years, the unfortunate truth is that many simulation systems are designed with an eye first to technology and only secondarily to more important learning factors such as cognition, training design, and effectiveness (Cannon-Bowers and Bowers, 2008; Salas et al., 1998). Researchers have yet to consistently integrate the science of training practically with simulation training (Salas and Kozlowski, 2010; Bell et al., 2008, Cannon-Bowers and Bowers, 2008). Incorporating what we know about training and learning (e.g., event- and competency-based training approaches) with simulations has been suggested as a way to remedy this situation (Cannon-Bowers et al., 1998; Fowlkes et al., 1998; Oser et al., 1999bb). That is, simulations and computer games should utilize training objectives, diagnostic measures of processes and outcomes, feedback, and guided practice. Though more research needs to be done in this area, preliminary studies (e.g., Tichon, 2007b; Colegrove and Bennet, 2006) have shown that, by designing simulations around specific events and measuring specific task performance, both learning and training analysis benefit greatly. See the review by Salas and colleagues (2008) for a list of principles for developing scientifically grounded simulation-based training. Finally, while it has been stated that an empirically verified framework regarding the processes involved in simulation-based training is lacking, Cannon-Bowers and colleagues (1998) developed a general model of simulation- and scenario-based training that includes the major components necessary for any good training program (see Figure 5). However, there has yet to be research done toward developing a comprehensive model regarding the antecedents

and processes of simulation-based training effectiveness. Promising steps have been made toward this end by Wilson and colleagues (2009) in their review of the literature on the processes of learning; their work theoretically links aspects of learning to common components of simulations and gaming. This work, then, is the closest there currently is to a comprehensive theory of simulation effectiveness and should serve as a jumping-off point for future research.

***Behavior Modeling Training***  Behavioral role modeling, or behavior modeling training, is another type of simulation that has been researched heavily in recent years. This technique has been shown to be effective in training for desirable outcomes such as organizational citizenship behaviors (e.g., Skarlicki and Latham, 1997), assertiveness (Smith-Jentsch et al., 1996bb), and various health care behaviors (Schwarzer, 2008). Taylor et al. (2005) conducted a meta-analysis of 117 studies on behavior modeling training, which reveals several characteristics of effective training regimens. Behavior modeling training led to the most transfer when trainees (1) were exposed to positive and negative models, (2) participated in scenario development, (3) set goals in training, (4) were trained alongside their supervisors, and (5) were extrinsically motivated to transfer training. Additionally, when trainees were cued as to which behavioral skills to attend to, skill learning was greatest; similar effects were found for length of training. Finally, it should be noted that the effects of behavior modeling training declined with time for declarative and procedural knowledge but remained stable or increased for results-level outcomes (e.g., productivity).

***Distance Learning***  Advances in technology have clearly impacted the way training systems are designed, and this trend is projected to continue indefinitely. As of 2006, approximately 36% of the nearly $110 billion per year training industry was devoted to technology-oriented training systems, and of this massive industry, 60% was self-paced online learning (Rivera and

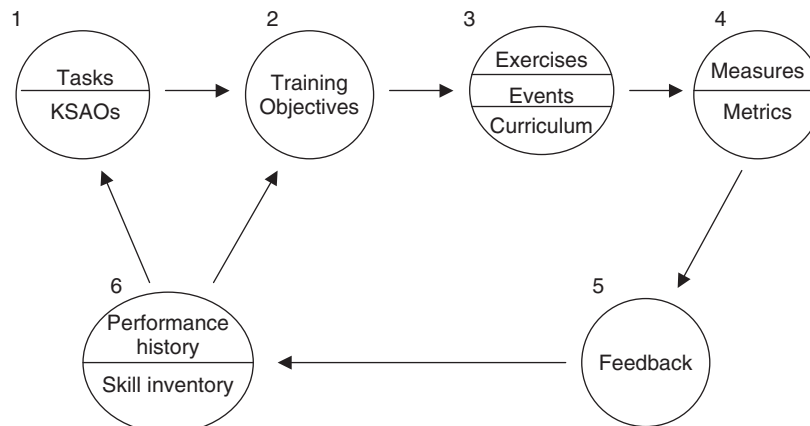

**Figure 5**  Components of scenario-based training. (From Cannon-Bowers et al., 1998.)

Paradise, 2006). While traditional (i.e., classroom-based) training methods continue to be the norm, organizations are with increasing frequency turning to technologies such as videoconferencing, electronic performance support systems, and online Internet/intranet training programs to supplement their development efforts. And while often used interchangeably in the literature, *distance learning* is the result of *distance training*. Distance training is a broad conglomeration of training strategies that are all characterized by a trainer/trainee separation of time and/or space. This broad training strategy encompasses several other methods discussed subsequently.

As with simulation-based training, there is a temptation for organizations to develop and/or adopt distance training methods without paying mind to the science behind the training. The increasing globalization of many organizations has encouraged the development and utilization of distance training strategies, but convenience is not an excuse for use. For training to be beneficial, it must be designed in accordance with the research on training and training effectiveness. Research is continually shedding more light on the nuances of distance learning. One of the major differences between distance learning and classroom learning is the issue of motivation. Without an instructor on hand to enforce (or encourage) behavior, much of the impetus of distance learning falls on the trainee. Accordingly, elements of training such as learner orientation (e.g., Klein, et al., 2006), learner control (e.g., Sitzmann et al., 2006; Orvis et al., 2009), and trainee reactions and self-efficacy (e.g., Sitzmann et al., 2008; Long et al., 2008) have been emphasized as key components of trainee motivation and performance in distance settings.

Other theoretical and logistical issues must be considered when designing and implementing distance training systems. Some of these include the importance of trainer/trainee face-to-face interactions, how to answer questions and feedback when physically and synchronously separated, where the training should fall on the content richness continuum, and the degree of learner control that should be provided. To date, these issues have been dealt with in piecemeal fashion (Bell et al., 2008). Kozlowski and Bell (2007) have presented a framework for distributed (distance) learning system design that incorporates what we know about training design and cognition as well as many available technologies. However, further research is required to determine if this framework is sufficient to address all these issues or if more theory is needed.

***E-Learning*** Any training that is conducted electronically refers to e-learning, though the vast majority of e-learning is computer based (Kaplan-Leiserson, 2002). E-learning has been defined as "a wide set of applications and processes, such as Web-based learning, computer-based learning, virtual classrooms, and digital collaboration" (Kaplan-Leiserson, 2002, p. 85). E-learning, as with many technologically oriented training designs, offers many advantages but brings with it a few new issues to consider as well. Some of the advantages of e-learning are (1) flexibility to make training mobile or local, (2) ability to incorporate multiple instructional media, (3) cost efficiency of continuing and reissuing training, (4) provision of learner control, and (5) allowing for synchronous or asynchronous training. A few issues to consider when implementing e-learning are (1) trainee motivation, (2) trainee self-efficacy and experience with computers, (3) higher start-up costs than classroom instruction, and (4) the fact that trainees ideal for e-learning are typically the employees with the least time to devote to training (Brown and Ford, 2002; DeRouin et al., 2004; Kozlowski and Bell, 2007; Klein et al., 2006; Shee and Wang, 2008).

Technological advancements have enabled e-learning to meet today's increasingly time-crunched training demands. However, recent surveys on the state and prevalence of e-learning have revealed some interesting trends. For example, some of the more advanced aspects of e-learning, such as mobile delivery or simulation, were ranked as being "rarely or never" used (Rossett and Marshall, 2010); typically these were avoided not only for economic reasons but also because of the difficulty involved with technology adoption. Rather, the most prevalent trend was that training and education typically occur in the classroom, with e-learning used as a supplementary tool (Rossett and Marshall, 2010). One arena in which the technological advances associated with e-learning have been adopted to a greater extent is distributed team training. Globalization and the increasing reliance on teams have ushered the modern workplace into an era categorized not only by teams as previously discussed but also by distributed teams. That is, team members are frequently no longer colocated but are "mediated by time, space or technology" (Driskell et al., 2003, p.3). This disconnect requires team members to rely on various communication technologies such as e-mail, videoconferencing, telephone, or faxing (Townsend et al., 1996). This dispersion, however, creates obvious problems for traditional, classroom-based training methods. The military has been most saliently affected by these team trends and has therefore exerted the most influence in the development of distributed team training methods.

Military efforts have developed the distributed mission training (DMT) system, which consists of multiple elements that combine to provide trainees with real-time, scenario-based training. These elements (real, virtual, and constructive) require coordination and communication with both real and virtual teammates (Carroll, 1999); performance on these tasks is analyzed and recorded, and trainees also receive feedback. Another key element of DMT systems is trainees' ability to access prior performance statistics from an online file and continue training from a save point. The development of DMT has resulted in two main training platforms that incorporate simulated training scenarios, virtual teammates, cognitive agents, and actual military personnel: Synthetic Cognition for Operational Team Training (SCOTT) (Zachary et al., 2001) and Synthetic Teammates for Realtime Anywhere Training and Assessment (STRATA) (Bell, 2003). While much of DMT research is military specific, the underlying principles regarding its development are relevant to any variety of distributed team training (Bell, 1999).

*Learner Control* As has already been intimated, learner control is a unique and important part of e-learning. Because learner control, which refers to "a mode of instruction in which one or more key instructional decisions are delegated to the learner" (Wydra, 1980, p.3), is a fairly general concept, it has been explored in the literature in a typically general fashion (Steinberg, 1977; Goforth, 1994; Brown and Ford, 2002; Orvis et al., 2009). The structure of e-learning lends itself perfectly to learner control. As a general rule, learner control is a major advantage e-learning has over more traditional training forms. For example, in their 2006 meta-analysis, Sitzmann and colleagues showed that Web-based instruction was not more effective than classroom instruction; however, when it allowed for learner control, it led to significantly more learning than classroom instruction. It has also been shown that the ability to control one's learning progress may be the most important aspect of the e-learning process (Shee and Wang, 2008). On the other hand, several studies have shown a negative relationship between learner control and training effectiveness (e.g., Tennyson, 1980; Murphy and Davidson, 1991; Lai, 2001). Content relevance has been suggested as a reason for these negative effects (DeRouin et al., 2004); trainee motivation also often has strong effects on the relationship between e-learning and training effectiveness (Klein et al., 2006).

*Collaborative Learning* Training can be augmented through collaborative learning strategies. Collaborative learning refers to any training situation where trainees receive training in groups. This refers not necessarily to team training (where teams are trained for team-based competencies) but simply to training situations where groups of trainees collaborate to learn. Certain aspects of the group experience facilitate learning more than individual learning efforts, especially when training efforts are targeted at increasing existing knowledge (Toomela, 2007). Dyadic tools that relied heavily on technology benefited military and nonmilitary pilots and navigators; however, when trainees were aversive to interaction, these benefits became nonsignificant (Arthur et al., 1996, 1997). Collaborative learning can provide opportunities for social learning (Shebilske et al., 1998) and can significantly reduce resource demands on the instructor (Shebilske et al., 1992). However, in collaborative distance and e-learning settings, the instructor–trainee interaction may be even more important than in colocated training settings (Marks et al., 2005).

*Error Training* As technology becomes more and more prevalent and workers shift from active players to passive observers in the work cycle, error training has become more and more prevalent in practice and research. Error training differs from proceduralized or error-avoidant training in that it encourages exploration and occasionally induces errors in the training process but also provides feedback that assists the trainee in improving performance (Frese and Altman, 1989; Heimbeck et al., 2003; Lorenzet, Salas, and

Tannenbaum., 2005). This better simulates the complexity of the real world, where employees are required to respond to variant situations, including the consequences of their own errors. Furthermore, the feedback provided in error management includes strategies for avoiding future mistakes. The advantages of error management over error avoidance are well-document in individual studies (e.g., Dormann and Frese, 1994; Ivancic and Hesketh, 1995) as well as in a recent meta-analysis of 24 empirical studies (Keith and Frese, 2008).

Error occurrence and error correction are the two main elements of error management training (Lorenzet et al., 2005). There are four ways the training designer can approach error occurrence in a program: (1) avoid, (2) allow, (3) induce, or (4) guide. Error-avoidant training guides the trainee through the program so as to either minimize or totally avoid errors; generally this is not beneficial for transfer of training, but in situations where the knowledge is procedural and static, this is actually the most effective approach (Keith and Frese, 2008). Allowing (but not inducing) errors, or exploratory learning, is helpful for transferring learning but can be difficult for trainers to anticipate where errors will occur, making the feedback process difficult (Gully et al., 2002; Keith and Frese, 2008). Inducing errors integrates a level of dynamism into the program such that changes are likely to induce errors; however, there is still no guarantee that errors will occur (Dormann and Frese, 1994). Guided error occurrence involves intentionally guiding trainees into a particular error, then providing strategies for avoiding that error. A recent meta-analysis has shown any kind of error training (i.e., *allow, induce,* and *guide*) to be more beneficial than error-avoidant training; furthermore, it was shown that error training strategies that involved inducing or guiding errors were more effective than simply allowing errors to occur (Keith and Frese, 2008).

Traditionally, two approaches to error correction have been utilized in designing error management training programs. Exploratory training design generally involves allowing trainees to struggle and work through errors until they solve any issues (Frese et al., 1991). This allows trainees to develop individualized strategies for addressing errors, but if trainees attribute errors incorrectly or come up with inappropriate strategies for error management, this may negatively impact adaptive transfer (Keith and Frese, 2008). The other approach is targeting feedback to correct errors (i.e., supported correction); feedback can be delivered either electronically or through a human instructor (Lorenzet et al., 2005). In a recent meta-analysis, Keith and Frese (2008) showed that providing error management instructions is significantly more effective than simple exploratory training.

A few general guidelines have been supported regarding error management training. Guided error training along with supported correction is generally the most effective error training (Lorenzet et al., 2005, Keith and Frese, 2008). While this tends to decrease within-training performance, trainees are better able to apply what is learned in training to different situations (Keith and Frese, 2008). This type of training also

leads to higher posttraining self-efficacy levels (Lorenzet et al., 2005). One caveat: Error-free training is equally effective (and more efficient) when training individuals for proceduralized, static tasks (Keith and Frese, 2008).

***Stress Exposure Training*** High-stress environments often add another layer of complexity onto training; the demands inherent in such situations can negatively impact trainees' cognitive resources and other abilities (Driskell et al., 2008). Stress exposure training (SET) incorporates increased situational demands into the training program so as to provide the KSAOs necessary to deal with real-world stressors (Driskell and Johnston, 1998). This form of training is especially important in situations where errors are likely to have major (and even life-threatening consequences). SET involves three stages of training: (1) identify common stressors and their effect on the job/task, (2) train trainees to deal with these potential stressors, and (3) gradually expose trainees to more of these stressors in a simulated training environment and provide feedback on their performance (Driskell et al., 2008). Importantly, SET has been shown to generalize across stressors (e.g., time pressure and high workload) and tasks (e.g., handling a hostage situation and pursuing a suspect) (Driskell et al., 2008).

***On-the-Job Training*** Job training can occur within or outside the actual job. Despite the increasing saliency of globalization and the trending toward various forms of distance learning, on-the-job training (OJT) remains one of the most prevalent forms of instruction (Paradise and Patel, 2009). OJT involves supervisors and/or trainers facilitating a training program in the exact physical and social contexts relevant to the specific job tasks (Wehrenber, 1987; Sacks, 1994; De Jong and Versloot, 1999). This training is distinguished from training that occurs on the job site but is separate from task performance (e.g., training workshops). OJT provides two main benefits to trainees and organizations: (1) training transfer is more likely to occur because it occurs in a totally relevant context and (2) tighter supervision within the training will prevent incorrect job strategies from being adopted by trainees.

Apprenticeship training is one form of OJT; it typically involves classroom instruction as well as supervision of job tasks and has traditionally been relegated to vocational trades (e.g., electricians). However, other types of organizations have begun to adopt an apprenticeship model (Goldstein, 1993). While the specifics of apprenticeship programs vary, typically they require trainees to be trained for a specified amount of time and to learn various essential skills before the trainee becomes a "journeyman" and is able to perform the job without supervision (Goldstein, 1993; Lewis, 1998; Hendricks, 2001). The European model of apprenticeship is markedly different from the U.S. method: Various European countries employ apprenticeship programs on a much larger scale and often incorporate higher learning into the apprenticeship experience (Steedman, 2005).

Mentoring is the other primary form of OJT and consists of a working relationship between job novice and expert (Wilson and Johnson, 2001). Industry reports indicate that formal and informal mentoring occurs in a large percentage of workplace settings (Paradise and Patel, 2009; Munro, 2009). The mentoring relationship has been shown to be related to many positive outcomes: increased communication and job satisfaction (Mobley et al., 1994; Forret et al., 1996), better leadership skills, more effective learning strategies, exhibiting more organizational citizenship behaviors (OCBs), and less stress and burnout (Munro, 2009). Mentoring is similar to apprenticeship in that the level of supervision allows the expert to model appropriate behaviors and monitor and correct the trainee's inappropriate behaviors (Scandura et al., 1996). Experts in the mentoring relationship also benefit; they practice vital skills while instructing trainees (Forret el al., 1996), receive greater satisfaction within the relationship, become aware of how others work, and form alliances and friendships within the workplace (Munro, 2009).

Informal learning is indirectly related to on-the-job training, as it refers to any time employees engage in learning that is not comprised of specific efforts at training. Jacobs and Park (2009) suggest a conceptual framework for delineating basic aspects of workplace learning on three domains: (1) on/off the job, (2) structured/unstructured, and (3) passive/active. These three domains interact to form eight kinds of workplace learning, with each form of learning requiring organizations, training designers, and learners to attend to different learning variables. For example, informal learning would primarily be categorized as unstructured and could either be active (i.e., conscious) or passive (i.e., during the course of regular work) and on or off (i.e., continuing education classes, personal study) the job. While not an official form of training, informal learning can serve the overall training function of improving employee performance, and organizations, leaders, and managers should be aware of a few things to facilitate informal learning in the workplace. The most impactful thing organizations can do to encourage informal learning is to create an environment conducive to continuous learning. This means (1) being supportive of employee efforts to informally learn, (2) providing opportunities to informally learn, and (3) making the tools and processes for learning available to employees that are interested in it (Tannenbaum et al., 2010). Other aspects of informal learning are relevant (Jacobs and Park, 2009; Tannenbaum et al., 2010) but are not the primary focus of this chapter on official training

### 5.6.3 Internationalization

It is a well known truth that the business world has become an increasingly global community (Tsui et al., 2007). Over 63,000 companies are involved on some level in the global marketplace (Chao and Moon, 2005), with many major companies (e.g., BP, Siemens, Honda) operating in over 100 countries (Adler and Gundersen, 2008). Constant, rapid advancements in technology coupled with an ever-increasing reliance on teams in organizations have enabled and necessitated (respectively) teams which are separated by time, space, and culture (Salas et al., 2008; Bell and Kozlowski,

2002). Unfortunately, the breakneck pace of such phenomena has yielded practice and research that are essentially out of sync (Shen, 2005). For example, while as far back as 2000 over 60% of companies offered some form of multicultural training, of those that did, a majority of this "training" consisted of one-day cultural debriefing seminars (Littrell and Salas, 2005). Insufficient expatriate training has resulted in millions of dollars lost for many organizations, due to early assignment termination, damaged relationships, burnout, and organizational departure (Littrell and Salas, 2005). And while expatriate studies continue to dominate the literature, strategies must be developed to address the issues inherent in all multicultural settings. The following sections, therefore, discuss research regarding the impact culture has on the individual (e.g., managers; see Shen, 2005) as well as the team.

Culturally oriented training has been given many names by practitioners and researchers: intercultural, diversity, multicultural, cross-cultural training, and so on. Some use these titles interchangeably, while others argue for differentiation (see Gudykunst et al., 1996). For the purposes of this chapter, we refer to culturally oriented training as *multicultural training*. The definition of multicultural training is then the development of behavioral, cognitive, and affective patterns in trainees that will make successful cross-cultural interactions more likely (Landis and Brislin, 1996; Morris and Robie, 2001). Like other forms of training, multicultural training should be intended not only to increase general cultural knowledge but also to improve skills, abilities, attitudes, and other characteristics relevant to cross-cultural success (Bhagat and Prien, 1996), which is typically attributed to personal adjustment, interpersonal adjustment, and task-relevant effectiveness (Littrell et al., 2006).

**Individual Cultural Training Strategies**   Multicultural training has typically focused either on directly providing cultural information to trainees or providing them with cultural experiences (Deshpande and Viswesvaran, 1992; Kealey and Protheroe, 1996). In addition to these methods, attribution, cultural awareness, cognitive behavior, interaction, and language training have all arisen as methods for multicultural training (Litrell and Salas, 2005). Following is a brief discussion of the most commonly used techniques:

1.  *Attribution Training*. Individuals tend to assign a reason to others' behaviors—this is known as attribution. The goal of attribution training is to help individuals better understand the attributions that individuals from other cultures may tend to make and to be able to take others' perspectives more effectively (Littrell and Salas, 2005; Befus, 1988). This not only provides a valuable set of skills but also serves to deepen the understanding and appreciation for other cultures of the trainee (Bhawuk, 2001).

2.  *Cultural Awareness Training*. The theory behind cultural awareness training is that in acknowledging one's own cultural background (and the biases inherent therein) cultural differences become more apparent as well as more understandable (Befus, 1988). This method may utilize a glut of training tools, from simulations, to role play, to group discussions (Thomas and Cohn, 2006; Bennett, 1986), with the ultimate goal being improved attitudes toward and strategies for interacting with culturally different others. An important characteristic of cultural awareness training is that the main goal inherent is the development of a culturally aware mindset. This mindset can manifest in either a static fashion (i.e., "I know how to be culturally aware") or a dynamic fashion (i.e., "I am always seeking to become more culturally aware"), but it is this mindset development that distinguishes cultural awareness training from other forms of multicultural training (Collins and Pieterse, 2007). Again, it is thought that by understanding what contributes to his or her own culture the trainee is better able to understand what should underlie other cultures.

3.  *Didactic Training*. Any form of cultural instruction that involves information giving can be considered didactic multicultural training. These may include information regarding travel, food, living conditions, and a host of other things. The format of didactic training is very similar to traditional classroom instruction in that it emphasizes cognitive goals (Bennett, 1986) such as understanding differences in political and economic structures between countries (Kealey and Protheroe, 1996; Morris and Robie, 2001). The ultimate goal of didactic multicultural training programs is to develop a working understanding of cultural factors to assist in future cross-cultural interactions (Littrell and Salas, 2005; Morris and Robie, 2001).

    Multicultural training can be delivered through various didactic media (e.g., informal briefings, cultural assimilators) (Littrell et al., 2006; Brewster, 1995) and are quite variable within. Informal briefings, for example, may be casual conversations and/or interviews with culturally experienced (and successful) individuals, such as past trainees or re/expatriates (Shen, 2005; Brewster, 1995; Kealey and Protheroe, 1996). "Briefings," however, are a fairly general term and can include lectures, videos, or information booklets on the targeted country/culture (Littrell and Salas, 2005; Grove and Torbiörn, 1993). Formal training strategies that are more in-depth may strategically cover topics such as religion, geography, history, and more (Littrell et al., 2006). Cultural assimilators consist of a variety of didactic methods that aim at teaching trainees to think like a target culture (Bhawuk, 1998, 2001). Trainees are presented with critical incident scenarios in which a response is required; in these tests, the goal is to select the response that an individual from the targeted culture would likely choose

(Kealey and Protheroe, 1996; Morris and Robie, 2001). Relational ideology training is a type of cultural assimilator that trains for emotion regulation and display in various cross-cultural settings (Sanchez-Burks et al., 2007).

4. *Experiential Training*. As the name suggests, experiential training involves having trainees learn by doing or *experiencing* a certain thing; this allows them to practice strategies and responses to various scenarios. In the case of multicultural training, it provides trainees with the skills and knowledge for interacting successfully with culturally different others (Kealey and Protheroe, 1996; Morris and Robie, 2001). Experiential training can not only impart intercultural skills and knowledge, but also serve the same purpose as attribution training, enabling trainees to see some things with the same mindset as culturally different others (Morris and Robie, 2001). Role playing, workshops, and simulations are among the most popular experiential training strategies for multicultural training (Littrell et al., 2006).

Simulations are excellent forms of experiential multicultural training, because they allow for safe practice opportunities (see the above section on simulations). BAFA BAFA is one of the most popular simulation games; in this game, trainees are assigned to one of two fictional, diametrically opposed cultures and then are tasked with interacting with individuals from the other culture (Bhawuk and Brislin, 2000). Since the development of BAFA BAFA, many more cultural simulation games have been developed. BARNGA (Steinwachs, 1995) is a card-based simulation in which trainees play card games with secretly different rules and are then required to play with other trainees with their own set of rules; this essentially emulates the process individuals must work through when dealing with others' cultural "rules." DIVERSOPHY is a cultural simulation that can be played on Second Life (a free, user-driven computer game). Intercultural simulation games have been applied in military, educational, business, and medical settings. For a deeper review of these simulations, see Fowler and Pusch (2010).

Initial reactions and anecdotal evidence tend to support the notion that individuals can be trained to be more cross-culturally savvy (Black and Mendenhall, 1990; Deshpande and Viswesvaran, 1992). However, there is a relative dearth of empirical evidence regarding the effectiveness of multicultural training, especially given the glut of work done on the theoretical and practical levels (Selmer, 2001; Selmer et al., 1998). This is especially vital, for as these training programs become more and more prevalent, it is becoming increasingly clear that effectiveness in these situations is not a guarantee. In a recent qualitative review of the literature, Kulik and Roberson (2008) showed that often multicultural awareness training programs were either marginally or not

at all effective. It therefore seems possible that certain moderators to the training–effectiveness relationship might exist, such as organization-, job-, and individual-level attributes (Bird and Dunbar, 1991; Bhagat and Prien, 1996). Recent studies have shown that the type of multicultural training, or its emphasis, may moderate the training relationship. For example, Waxin and Panaccio (2005) found that training type significantly moderated the training–expatriate adjustment relationship such that experiential training programs were significantly more effective than didactic programs. Similarly, a study comparing three emphases for diversity training (i.e., cultural awareness, attribution, and cultural skill-training) showed that only skill-based training was significantly related to intent to transfer training (Roberson et al., 2009). Further studies are needed to quantitatively explore the effectiveness of cultural training programs.

***Multicultural Team Training Strategies***  As the prevalence of teams has increased along with the saliency of globalization, multicultural teams have naturally become more and more common. Accordingly, multicultural team training strategies have become a necessity. To address this need, traditional team training programs have been adapted so that trainees are prepared for the unique aspects inherent in multicultural team interactions. Five domains typically characterize multicultural team training programs: (1) enhancing specific aspects of performance through improvement of general team characteristics, (2) using a traditional team performance framework, (3) applying specific training tools and feedback, (4) utilizing a multimethod training method, and (5) training in a limited time frame (Salas and Cannon-Bowers, 2001). Following is a brief review of three common multicultural team training strategies that have been shown to foster greater multicultural team performance and effectiveness.

1. *Team Leader Training*. Cultural differences add a unique layer of complexity to teams, and if team leaders are unable to effectively manage this complexity, teams will fail (Moore, 1999; Salas et al. 2004). Multicultural team leader training typically does not consist of specific training; rather, training for leadership and training for cultural awareness occur separately. For example, team coaching, which facilitates better communication (Kozlowski et al., 1996), can help mitigate poor communication in multicultural teams (Thomas, 1999). Martin and Lumsden (1987) provide a good overview of coaching strategies (e.g., praise or reward desired behaviors, foster encouraging environment).

However, few training programs exist to date that specifically provide leaders with the skills to manage multicultural teams (Burke et al., 2005). "Functional Learning Levers—The Team Leader Toolkit" (FuLL TiLT, Burke et al., 2005) is a program that trains good leadership skills *while taking culture into account*. This training

program incorporates experiential learning and critical incident studies to expose trainees to positive and negative models of multicultural leadership behaviors, with the end goal being trainees' understanding and development of culturally appropriate leadership skills. This is an important step to multicultural team performance, as research has shown variation in leadership style effectiveness across cultures (Ochieng and Price, 2009).

2. *Team Building*. While team building is certainly not unique to multicultural training, it has been shown to be particularly useful in this context. The essence of team building is including a group of individuals in a change development/implementation process (Salas et al., 1999). Team building is frequently used to develop interpersonal relationship skills in multicultural settings (Butler and Zander, 2008), foster trust in culturally diverse teams (Ochieng and Price, 2009), and aid the adjustment process for expatriates (Shay and Tracey, 2009). Team building models can be categorized by one (or more) of four approaches: *goal setting, interpersonal relations, problem solving*, and *role clarification* (Lintunen, 2006). Team *goal setting* allows members to experience the breadth of other team members' perspectives and skills (Watson et al., 1993). An *interpersonal relations* approach encourages the development of healthy relationships within the team. The increased trust resulting from this approach is especially salient in multicultural teams where mistrust often hinders performance (Distefano and Maznevski, 2000; Triandis, 2000). *Problem solving* in the multicultural team is designed to identify and address problems within the team (Adler, 1997). Developing strategies for proactive problem solving enables more efficient future problem solving (Daily et al., 1996). *Role clarification* involves helping team members identify the purpose of each member in the team; this allows for more effective distribution of work. This approach is especially necessary in multicultural teams, where language and social differences can lead to communication and work distribution issues (Steiner, 1972; Thomas, 1999; Hofstede, 1980).

3. *Role Playing*. A third team training strategy effective in multicultural contexts is role playing. Role playing involves trainees interacting with other trainees through scripted scenarios aimed at either (1) enculturation, or learning about one's own culture (Roosa et al., 2002), or (2) acculturation, or learning about another culture. *Enculturation* is a goal of role playing shared with cultural awareness training in that it refers to becoming more aware of the biases, prejudices, and norms inherent in one's own culture. *Acculturation* is similar to didactic training in that its focus is on creating awareness of *other* cultures. When utilizing both these approaches, trainees can become more culturally aware and proficient. Role playing is a form of behavior modeling training (BMT); see the previous section on BMT for guidelines on developing effective role playing training programs. One advantage team-based role playing has over individual (or computer-assisted) approaches is that it allows for experiencing multiple perspectives of cultural interactions. Therefore, multicultural team training programs using role playing should incorporate multiple perspective-taking opportunities into the program.

## 5.7  Program Content

After conducting all the appropriate analyses, developing training objectives, selecting the instructional strategy, and designing the training, the actual content of the program needs to be decided upon (Clark, 2000). This entails structuring the delivery of content in a logical flow and addressing all the training needs and objectives. Accordingly, all tasks trainees are provided with should serve a direct purpose toward achieving training goals. This will allow trainees to focus on the training objectives and avoid distractions that might negatively impact the knowledge structures the trainee is forming during training. Finally, delivering the program content in a logical structure will allow the training to be easily implemented in other contexts and will standardize the entire process.

## 5.8  Summary

There exists an abundance of research on the design of training systems. While it may be tempting to design training based on common sense or personal knowledge, it is vital for the training designer to leverage this extensive knowledge base. Training designers must consider not only the content and the instructional strategy but also external factors such as organizational and individual characteristics when designing a training program for maximal effectiveness.

## 6  TRAINING DEVELOPMENT

The next phase identified in the ISD model involves developing and refining the components of the training program. This includes preparing course materials, creating practice activities, and developing a system for testing and measuring trainee performance.

## 6.1  Practice Scenario Development

Consistent with the previous review (Salas et al., 2006b), research continues to emphasize the critical role of practice in successful training programs. Practice enhances learning by refining knowledge structures, or mental models, within meaningful contexts (Murthy et al., 2008). In addition, practice provides an opportunity to assess performance, enabling trainees to obtain feedback and make adjustments in behavior when weaknesses are identified. Furthermore, practice can promote the transfer of training by allowing trainees to gain experience

applying learned competencies in various contexts. In order to reap these benefits, however, practice scenarios should be carefully designed prior to the training period. Doing so allows trainers and researchers to maintain control over the practice period by standardizing the selection, presentation, and timing of the competencies to be practiced. Practice scenarios can vary greatly in their degree of realism, ranging from very high fidelity (e.g., full motion simulators) to very low fidelity (e.g., role-play activities). As both types have proven to be effective (e.g., Vechhi et al., 2005; Seddon, 2008), the level of realism should be related to the content and goals of the training program. Practice scenarios should also incorporate a range of difficulty levels and should allow trainees to respond in different ways rather than requiring clear-cut answers. Additionally, learning and transfer can be facilitated by enabling trainees to practice their skills on multiple occasions and in various contexts (Prince et al., 1993).

## 6.2 Performance Measures

Performance measures also remain a key contributor to the success of training initiatives. Measuring performance provides an opportunity to assess or diagnose trainee competence and provide feedback, both of which are central to the learning process. Arguably, training cannot effectively lead to changes in knowledge and behavior without incorporating measures of performance. Strong performance measures can ultimately feed back on the success or failure of training and highlight any deficiencies to guide ongoing improvements (Tichon, 2007b). Performance measurement can be facilitated by following certain preparatory guidelines. First, steps can be taken to simplify the measurement process for those responsible for making assessments. Opportunities for measurement should be incorporated into carefully designed practice scenarios. Doing so ensures that target competencies are practiced and measured appropriately. Instructors can thus easily identify trigger points at which performance should be observed and recorded.

Second, an overall system for measuring performance and providing feedback should be established prior to training. This can be a complicated process, as multiple factors should be considered when determining the appropriate strategy. For example, objective measures of performance, such as timing or number of errors, can be obtained automatically through the use of high-technology simulations. While this is a convenient way to collect performance measures, it is not ideal for all practice scenarios because it cannot easily capture data related to the processes (e.g., communication, decision making) used to reach performance outcomes. Team performance in particular cannot easily be captured due to the dynamic natures of teams and team processes. The limitations associated with automatic performance measures are especially apparent during periods of high workload (e.g., those experienced by trauma teams). Under such conditions, teams often communicate and coordinate at the implicit level, and as a result, significant processes become impossible for simulation-based systems to detect. In contrast,

human observers can draw inferences by observing and assessing behaviors using preestablished criteria such as checklists or observation forms. Utilizing human observers, however, could introduce errors and bias into your performance measures. To reduce such issues, at least two observers should be used and steps should be taken to establish reliability (i.e., consistency between evaluators' ratings) and validity (accuracy of evaluators' ratings) (e.g., Brannick et al., 2002; Holt et al., 2002). Choosing between objective and subjective performance measures essentially requires a trade-off that should be guided by the content and goals of the training program.

Lastly, training and practice should be designed to incorporate multiple opportunities for performance measurement. Assessments should be taken on various occasions throughout the simulation in order to gain an accurate representation of trainees' performance.

## 6.3 Summary

Developing practice scenarios and performance measurement strategies are critical steps toward the success of any training program. Learning and transfer are facilitated when trainees are given opportunities to apply target competencies and receive feedback that can guide future performance.

## 7 TRAINING IMPLEMENTATION

At this point, the training program should be fully developed and the organization should prepare to implement it. During this phase, a training location with the appropriate resources (e.g., computers for computer-based training) should be selected. Instructors should be trained, training should be pilot tested, and any final adjustments should be made (Clark, 2000). Once this has been completed, the training program will be fully prepared for delivery. During the implementation phase, steps should be taken to foster a learning climate and support transfer and maintenance (Salas and Stagl, 2009). For example, training objectives should be clearly communicated, and trainees should be prompted to set proximal and distal goals.

## 8 TRAINING EVALUATION

Just as important as developing and implementing training is the process of evaluating the effectiveness of the training program. It is critical not only to determine whether or not training was effective but also to evaluate how or why it was effective or ineffective. Without this phase, it is impossible to make improvements to the training program or re-create it for use in different situations. Training evaluation is thus essential to carrying out the overall goals of a training program. Evaluation concerns and methodologies will be discussed below.

### 8.1 Evaluation Design Concerns

Training evaluation is essentially a system for measuring the intended outcomes or goals of the training program.

The evaluation process includes the examination of such things as measurement, design, learning objectives, and acquisition of the target knowledge, skills, and abilities. Training evaluation is vital to the overall training process because it allows organizations and researchers to determine whether or not training led to meaningful changes in performance and other organizational outcomes of value.

Unfortunately, many organizations do not carry out the evaluation phase after implementing their training program due to the high costs and intensive labor often associated with doing so (Salas and Stagl, 2009). Evaluation can be a difficult process because it might require specialized expertise, a team of people to collect and analyze performance data, and it might need to be conducted in the field or on the job. Moreover, organizations sometimes avoid evaluating their training due to the politics involved or the possibility of uncovering bad news. Fortunately, researchers have taken strides to develop innovative, practical systems for facilitating the evaluation process. For example, evaluation can be simplified by basing the method of evaluation on the specific evaluation questions of interest (Sackett and Mullen, 1993) and by assessing performance differences between training-relevant content and training-irrelevant content following the training period (Haccoun and Hamtiaux 1994). Training evaluation research has spanned multiple training domains such as team training (e.g., Salas et al., 1999), stress training (e.g., Friedland and Keinan, 1992), and computer training (e.g., Simon and Werner, 1996), to name a few.

Since the previous review (Salas et al., 2006b), researchers have continued to develop and refine training evaluation techniques. Many have emphasized the value of assessing multiple training outcomes separately in order to gain a complete picture of the training's overall effectiveness. For example, taking a "voice-centered" approach in which trainees' perceptions of the training are analyzed (Fairtlough, 2007) and assessing trainees' level of satisfaction with the training program (Fullard, 2007) continue to garner support in the literature as effective evaluation strategies. Researchers have also argued for the use of six evaluation levels, namely reactions, learning, job behavior, job performance, organizational team performance, and wider, societal effects (Galanour and Priporas, 2009). Generally, research continues to provide evidence suggesting that carefully implemented training programs are in fact effective. What is less clear, however, is how best to evaluate them. High-caliber, comprehensive training evaluations are unfortunately rare (e.g., Ralphs and Stephan, 1986). In the following sections, we will discuss some of the costs and procedures involved in the evaluation process.

### 8.2  Costs of Training Evaluations

Various practical concerns are often major deterrents to the evaluation of training programs. Implementing the evaluation can put a strain on both temporal and monetary resources. Researchers have explored ways to reduce the costs of training evaluation. For example, trainers can assign different numbers of participants to training and control groups (Yang et al., 1996). Having unequal group sizes with a larger overall sample size may allow for the same level of statistical power at a lower cost. Training designers can also substitute a less expensive proxy criterion measure in place of the target criterion when evaluating training effectiveness. This technique increases the sample size needed to achieve a given statistical power while expending fewer resources. Training designers may need to negotiate a trade-off between reducing costs through proxy criterion measures and potentially increasing costs by utilizing a larger sample size (Arvey et al., 1992).

### 8.3  Kirkpatrick's Typology and Beyond

The most widely used evaluation methods are those based on Kirkpatrick's (1976) four-level model (Anguinis and Kraiger, 2009). In this approach, training is evaluated based on four criteria: (1) trainee reactions (i.e., what trainees think of the training), (2) learning (i.e., what trainees learned), (3) behavior (i.e., how trainees' behavior changes), and (4) organizational results (i.e., impact on organization). Reactions can be assessed by asking trainees if they liked the training and if they perceived it as useful. Tests and exercises can be used to measure the degree to which trainees have acquired the trained competencies. Behavior changes can be measured by observing trainees' performance in the workplace. Finally, organizational results can be evaluated by examining such things as turnover, costs, efficiency, and quality. Each of these levels is further described in Table 4.

Since its inception, Kirkpatrick's (1976) multilevel approach has been widely utilized and supported. Both individual studies (e.g., Noe and Schmitt, 1986; Wexley, 1986) and meta-analytic reviews (Burke and Day, 1986) have garnered support for its use as an effective method for evaluating training. Despite its widespread use, support for the overall framework is limited, as most studies have evaluated only one of the four levels. Specifically, trainee reactions (e.g., Bunker and Cohen, 1977) and trainee learning (e.g., Alliger and Horowitz, 1989) are most commonly evaluated, while the other levels are largely ignored. Salas and colleagues (2001), for example, examined the literature on CRM training and found that 41% of the studies they reviewed used some levels of the Kirkpatrick model to evaluate their training, but the vast majority of them limited their evaluation to only one or two of the levels, typically reactions and learning or reactions and behavior. The results of this review were thus ambiguous and incomplete, highlighting the importance of conducting comprehensive training evaluations.

The recognition of such issues has led to various revisions of the original framework and changes to the way it is used. In regards to measurement, it is important to note that Kirkpatrick's model was designed for a relatively inexperienced audience. As such, researchers have been quick to point to conceptual flaws and other limitations of the model (Snyder et al., 1980; Clement, 1982; Alliger and Janak, 1989). For example, the framework fails to incorporate relevant trainee outcomes such as motivation and self-efficacy

**Table 4  Kirkpatrick's (1976) Multilevel Training Evaluation Typology**

| Level | What Is Being Measured/Evaluated | Measurement | Sample Questions |
|---|---|---|---|
| 1. Reactions | • Learner and/or instructor reactions after training<br>• Satisfaction with training<br>• Ratings of course materials<br>• Effectiveness of content delivery | • Self-report survey<br>• Evaluation or critique | • Did you like the training?<br>• Did you think the trainer was helpful?<br>• How helpful were the training objectives? |
| 2. Learning | • Attainment of trained competencies (i.e., knowledge, skills, and attitudes)<br>• Mastery of learning objectives | • Final examination<br>• Performance exercise<br>• Knowledge pre- and posttests | • True or false: Large training departments are essential for effective training.<br>• Supervisors are closer to employees than is upper management. |
| 3. Behavior | • Application of learned competencies on the job<br>• Transfer of training<br>• Improvement in individual and/or team performance | • Observation of job performance | • Do the trainees perform learned behaviors?<br>• Are the trainees paying attention and being observant?<br>• Have the trainees shown patience? |
| 4. Results | • Operational outcomes<br>• Return on training investment<br>• Benefits to organization | • Longitudinal data<br>• Cost–benefits analysis<br>• Organizational outcomes | • Have there been observable changes in employee turnover, employee attitudes, and safety since the training? |

*Source*: Adapted from Childs and Bell (2002) and Wilson et al. (2005).

(Gist et al., 1988; Gist, 1989; Tannenbaum et al., 1991). Further, measures relating to the value of training, such as content validity (Ford and Wroten, 1984), cost-effectiveness, and utility (Schmidt and Bjork, 1982; Cascio, 1989), are not considered. Finally, because learning is conceptualized as increases in declarative knowledge, Kirkpatrick's typology is difficult to merge with more recent developments in learning theory, such as cognitive skill acquisition (Anderson, 1982; Ackerman, 1987).

In response to these concerns, efforts have been made to improve individual levels of Kirkpatrick's framework and to rebuild or add to the model as a whole. Several researchers, for example, have criticized the first level of the model, reactions, for its use of self-report measures of trainee reactions. Self-report measures have been very popular and arguably overused due to their ease of use, but they do not necessarily provide an accurate or complete representation of training effectiveness. Specifically, measuring the degree to which trainees liked the training does not provide information regarding their learning or performance and thus does not reflect the efficacy of the training program (Alliger et al., 1997). Kraiger and colleagues (1993) addressed this issue in their discussion of three outcomes they deemed essential to training evaluation: affective (i.e., reactions), cognitive (i.e., learning), and skill-based (i.e., behavior) outcomes. The first level, reactions, includes more traditional measures of trainee affect, or how much they liked the training, but also includes a measure of perceived utility, or the degree to which trainees considered the training useful. Utility judgments indicate

the extent to which trainees believe the training will help them on their jobs and can provide information about their learning and potential application of trained competencies. In fact, perceived utility has consistently demonstrated a positive relationship with the transfer of training (Burke and Hutchins, 2007). The authors did not eliminate affective reactions from their model, however, as such measures can still offer information of value. Evaluators can gather information about organizational factors, such as organizational support, through trainees' reports of their feelings toward the training. Thus both forms of trainee reactions were incorporated in the revised framework, and both are often included in more modern models of training evaluation.

The second level, learning, is focused on determining whether or not trainees successfully learned the competencies targeted in the training program. As mentioned above, learning has traditionally been assessed through declarative knowledge tests but can also be measured through procedural tests immediately following training. Trainees' application of learned competencies on the actual job is measured in the behavioral level of evaluation, in which changes in behavior are examined after the training period, in the work environment. Finally, organizational outcomes such as reduced costs and improved performance are assessed at the highest level of evaluation, results. Evaluation at this level is also concerned with the validity of the training program. Intraorganizational validity (i.e., is performance consistent across multiple groups of employees?) and interorganizational validity (i.e., will the training program in one department be effective in another?), for

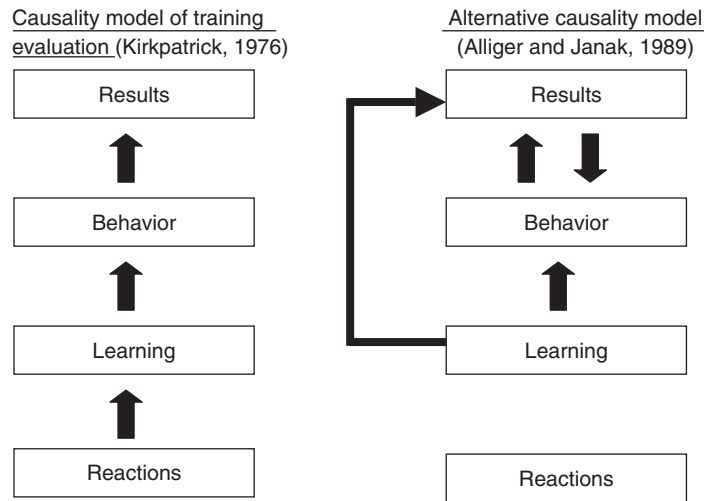
(Alliger and Janak, 1989)


Figure 6    Comparison of two training evaluation models.

example, are important results to examine. Unfortunately, this type of data is rarely collected due to the high costs and labor required to do so.

Alliger and colleagues (1997) also refined and expanded the Kirkpatrick typology based on their meta-analytic review of the literature (Alliger and Janak, 1989). As depicted in Figure 6 and Table 5, their framework extended and clarified the methods involved in the original typology. Specifically, the authors created different classifications for trainee reactions and learning and emphasized the evaluation of the transfer of training rather than the broader behavior category.

Like Kraiger, et al.'s (1993) model, the reaction phase is divided into two categories: affective reactions and utility judgments. Importantly, the learning phase is also comprised of multiple categories, including immediate knowledge, knowledge retention, and behavior/skill demonstration. Including multiple aspects of these levels enables evaluators to gain a more complete understanding of training effectiveness. The authors also argued for the use of multiple evaluation methods such as multiple-choice tests, open-ended questions, and the recall of facts. The model is further strengthened by the behavior/skill component of learning evaluation in which trainees' performance is assessed within the training context. Simulations, performance ratings, and behavioral role-plays can indicate the extent to which trainees have acquired the target competencies.

The last two phases of the revised model include transfer and results. Transfer is evaluated after the training has been completed and trainees have returned to their jobs. Evaluations of transfer are different than those of knowledge retention because they emphasize on-the-job performance, which requires the maintenance and generalization of trained competencies. The results phase is concerned with broad training outcomes such as productivity gains, improved customer satisfaction, reduced production costs, and increased profits. While

each of these evaluation phases can provide valuable information about training effectiveness, it is important to note that evaluation results may or may not be related to training. Such information is difficult to capture and is subject to the influence of several organizational factors aside from training. Evaluation results should thus be interpreted and acted on with caution.

Although revisions to the original Kirkpatrick typology have addressed several of its limitations, other concerns have arisen in the literature. Kraiger and Jung (1997), for example, argued for the use of instructional training objectives in the evaluation of learning outcomes. Other scholars have developed methods for assessing learners' knowledge and in skills in specific domains (Goldsmith and Kraiger, 1997). More recently, researchers have continued to refine the original model. As mentioned previously, Galanou and Priporas (2009) proposed the use of six evaluation levels: reactions, learning, job behavior, job performance, organizational team performance, and wider, societal effects. Other studies have reevaluated specific phases of the model such as trainee reactions. A recent study suggested the adoption of a "voice-centered" approach to training evaluation in which the trainees' in-depth description of the training program is the primary unit of analysis (Fairtlough, 2007).

Despite its limitations and criticisms, the Kirkpatrick (1976) typology remains one of the most widely used frameworks for guiding training evaluation. The original model has served as a valuable foundation for researchers and practitioners alike. Additionally, research shows that much can be gained from supplementing and revising the individual phases of the model and its overall structure.

## 8.4  Summary

It is critical for organizations to evaluate the effectiveness of their training following the completion of a

**Table 5  Alliger et al.'s (1997) Augmented Kirkpatrick Training Taxonomy**

| Step | | Definition |
|---|---|---|
| 1. Reactions | | |
| | a. Affective reactions | Measures emotional self-report of trainees given immediately, with little if any thought; impressions. |
| | b. Utility judgments | Evaluates trainee opinions or judgments about the transferability and utility of the training; behaviorally based opinions. |
| 2. Learning | | |
| | a. Immediate knowledge | Assesses how much trainees learned from training (i.e., how much they know about what they were trained). Uses multiple choice, open-ended questions, lists, etc. |
| | b. Knowledge retention | Assesses what trainees know about training, much like immediate knowledge tests, but administered after some time has passed, to test retention. Used in combination with or instead of immediate knowledge tests. |
| | c. Behavior/skill demonstration | Measures behaviors/skills indicators of performance exhibited during training as opposed to on the job. Uses simulations, behavioral reproduction, ratings of training performance, and performance-centered scorings in classes. |
| 3. Transfer | | Measures output, outcomes, and work samples to assess on-the-job performance. Measured some time after training to assess some measurable aspect of job performance. Assesses transfer of training to job setting. |
| 4. Results | | Assesses what organizational impact training had after the fact. Uses measurement of productivity gains, customer satisfaction, any change in cost, an improvement in employee morale, and profit margin, among others. Measurement is often difficult, due to organizational limitations and because results are the most distal from training. Caution should be used, however, because results are often regarded as the basis for judging training success, but judgments are often based on false expectations. |

training program. Kirkpatrick's typology has served as a valuable springboard for various evaluation models and tools. Although practical concerns and high costs prevent many organizations from conducting evaluations, doing so can inform future training programs and contribute to organizations' future success.

## 9  TRANSFER OF TRAINING

The transfer of training refers to the extent to which trained competencies are applied, generalized, and maintained in the work environment (Baldwin and Ford, 1988). Transfer leads to meaningful changes in job performance and thus is essentially the primary goal of any training initative. As such, the transfer of training remains a prominent area of interest for both researchers and organizations alike. The previous review highlighted research indicating that transfer is influenced by factors such as organizational context, delay between training and use on the job, and situational cues and consequences. Since then, researchers have provided ample evidence that transfer is also influenced by the three main components of Baldwin and Ford's (1988) model of transfer: trainee characteristics, training design, and the work environment. Several trainee characteristics, for example, have exhibited consistent, positive relationships with the transfer of training. Meta-analytic findings show a strong correlation between cognitive ability and positive transfer outcomes (Blume et al., 2010). Trainees higher in cognitive ability are more likely to successfully acquire, utilize, and maintain trained competencies in the appropriate contexts. Self-efficacy, or one's belief in their ability to accomplish a task (Bandura, 1982), has also been linked to training transfer through meta-analysis (Blume et al., 2010). Research suggests that self-efficacy partially contributes to transfer through its influence on motivation (e.g., Chiaburu and Linsday, 2008), another trainee characteristic that positively predicts the transfer of training (Baldwin et al., 2009). Specifically, pretraining motivation, motivation to learn, and motivation to transfer have all demonstrated significant relationships with the transfer of trained competencies. More recently, perceived utility, or the value associated with participating in training, has also emerged as a predictor of training outcomes (Burke and Hutchins, 2007). Transfer is enhanced when trainees perceive a clear link between trained competencies and valued job outcomes (Chiaburu and Lindsay, 2008) and when training instructions match job requirements (Velada et al., 2007).

Transfer can also be facilitated through the use of certain training design and delivery methods. Since the last review (Salas et al., 2006b), no major research has negated the reported effectiveness of behavioral modeling techniques. Behavioral modeling is a learning approach which incorporates clearly defined explanations of behaviors to be learned, models displaying the effective use of these behaviors, opportunities for trainees to practice learned skills, and the provision of feedback and social reinforcement (Taylor et al., 2005).

## 9.1  Posttraining Environment

In addition to the characteristics of trainees and training design, those of the posttraining environment also play a significant role in the transfer of training. By facilitating or hindering the use of trained competencies, environmental factors largely determine whether or not learned behaviors are exhibited once trainees return to the work setting. If the posttraining environment does not encourage the transfer of target competencies, even well-designed, properly implemented training programs will fail to yield long-term behavioral change. Several components of the posttraining environment have been shown to contribute to transfer outcomes. A positive transfer climate, for example, encourages trainees to apply target knowledge and skills to the job (e.g., Colquitt et al., 2000). Transfer climate has been described as observable or perceived situations that inhibit or facilitate the use of learned skills (Rouiller and Goldstein, 1993). Such situations might include cues that prompt trainees to use new skills, consequences for the correct, incorrect, or lack of use, and social support in the form of feedback and incentives. Research continues to show a significant relationship between transfer climate and training outcomes (e.g., Blume et al., 2010; Gilpin-Jackson and Busche, 2007; Burke et al., 2008).

Supervisor and peer support have also exhibited strong relationships with the transfer of training (e.g., Blume et al., 2010). Supervisor support can be manifested in various ways. Goal setting, for example, can be used to enhance transfer outcomes. Supervisors should prompt employees to set goals for utilizing new competencies in the workplace (Burke and Hutchins, 2007). Supervisors can also provide support by providing recognition and rewards (Salas and Stagl, 2009), communicating expectations (Burke and Hutchins, 2007), and maintaining a high level of involvement (Gilpin-Jackson and Busche, 2007; Saks and Belcourt, 2006). Trainees can support each other by observing one another using trained skills, coaching each other, and sharing ideas about course content (Gilpin-Jackson and Busche, 2007; Hawley and Barnard, 2005).

Not surprisingly, new competencies will not transfer to the workplace unless employees are given ample opportunities to apply them (Burke and Hutchins, 2007). Research shows that deficient time, resources, and opportunities to perform can seriously hinder the use of trained knowledge and skills on the job (e.g., Clarke, 2002; Gilpin-Jackson and Busche, 2007). Transfer is enhanced when trainees are provided with sufficient opportunities and resources for the application of their new skills. Additionally, the delay between training and opportunity to perform should be minimized. Transfer can be further facilitated through the use of follow-up activities (Salas and Stagl, 2009). After, action reviews, for example, debrief trainees, provide further education and enable trainees to reflect on their experiences through practice and discussion. Posttraining interventions such as relapse prevention, self-management, and goal setting can all serve to promote the transfer of training (Baldwin et al., 2009).

Finally, trained competencies are transferred more readily when trainees perceive a continuous learning culture. A continuous learning culture encourages the acquisiton of new knowledge, skills, and attitudes by reinforcing achievement and encouraging innovation and competetion (Tracey et al., 1995). When this climate is ingrained in an organization, learning will be part of the daily work environment, and employees will be more likely to utilize new competencies on the job.

## 9.2  Job Aids

The transfer of training can also be facilitated through the use of job aids. Job aids are tools that are used to assist in the performance of a job or task (Swezey, 1987). Job aids are beneficial because they reduce the amount of time employees need to spend in training, requiring them to spend less time away from their jobs. They can also improve performance by minimizing the cognitive load required to memorize job information, thus freeing up cognitive resources that can be directed toward other aspects of performance. Job aids can be particularly useful in stressful environments in which critical components of a task are more likely to be forgotten or unintentionally omitted. Several types of job aids exist, including informational, procedural, and decision making and coaching. These are listed in Table 6 and further discussed below.

### 9.2.1  Informational Aids

Informational job aids contain material similar to that of on-the-job manuals and reference books. These materials are critical when job information is impossible to memorize (e.g., an aircraft maintenance manual). They are also used to reduce the cognitive demands (e.g., recall of memorized information) associated with performing the job. Informational job aids typically include facts relating to names, locations, dates, and times that are relevant to the job (Rossett and Gautier-Downes, 1991) and are available in paper or electronic formats. Such aids enhance performance by making pertinent job information easily accessible.

**Table 6  Types of Job Aids**

| Type | Description | When to Use |
|---|---|---|
| Informational | Provides access to large amounts of information, such as telephone directory or online database. | During task |
| Procedural | Provides step-by-step instructions for completing a task, such as directions for installing a faucet. | During task |
| Decision making and coaching | Provides a heuristic to guide the user through a thought process to choose the best solution. | Before, during, and after task |

*Source:* Originally published in Salas et al. (2006b).

### 9.2.2  Procedural Aids

Procedural job aids provide step-by-step instructions explaining how to complete a task (Swezey, 1987). In addition to illustrating which actions to take in sequential order, they often also include feedback regarding what the results of each step should look like. Checklists, for example, are a type of procedural aid used to assist employees in remembering and completing each component of their task. Though they have traditionally been provided in paper formats, many companies now offer them online or through other electronic mediums.

### 9.2.3  Decision-Making and Coaching Aids

Decision-making and coaching job aids provide heuristics, or references that guide employees to think a certain way in order to determine the best decision or solution to a problem (Rossett and Gautier-Downes, 1991). Unlike procedural aids, they do not provide detailed, sequential information. Instead, they provide cues, such as ideas or questions, which guide the user toward the path that will lead to the optimal solution. The specific steps used to reach the solution are free to vary.

Job aids have traditionally been implemented when employees are unsure about job information or how to complete a task. Decision-making and coaching aids, however, can be used prior to and after the specific time they are needed. As such, these types of job aids can also be considered training aids because they provide learning opportunities that can benefit future task performance.

Job aids can serve to enhance performance in various contexts. Table 7 provides guidelines describing situations in which job aids should be implemented.

### 9.2.4  Development of Job Aids

To develop a job aid, a task analysis must first be conducted in order to identify the knowledge, skills, equipment, and technical data required to perform the task (Swezey, 1987). The specific steps used to perform the task as well as the appropriate sequence of those steps should also be determined. Once this information

**Table 7  Situations When Job Aids Should Be Used**

- The performance of a task is infrequent and the information is not expected to be remembered.
- The task is complex or has several steps.
- The costs of errors are high.
- Task performance is dependent on knowing a large amount of information.
- Performance depends on dynamic information or procedures.
- Performance can be improved through self-correction.
- The task is simple and there is high turnover volume.
- There is not enough time for training or training resources are not available.

*Source*: Adapted from Rossett and Gautier-Downes (1991).

has been gathered through task analysis, the type of job aid can be determined and the tool can be fully developed. Upon completion, the job aid should be tested and modified to ensure its effectiveness. Further, job aids should be updated as information, procedures, or decision-making processes change (Rossett and Gautier-Downes, 1991).

### 9.2.5  Training Aids

Job aids can also be developed for use during training. Training aids differ from job aids in that they are not used to complete a specific task on the job, but rather, they aid in skill and knowledge acquisition during training. Specifically, training aids are documents, manuals, or devices that are designed to assist trainees in learning the appropriate competencies that are associated with a task or job (Swezey, 1987). Like other types of job aids, training aids are increasingly available in computer-based formats as well as more traditional paper formats.

### 9.2.6  Examples of Job Aids

Various types of job aids are available and implemented in organizations. We discuss two commonly used job aids, namely, manuals and decision support systems.

***Manuals***  Manuals can be used to present both informational and procedural job aids. Information that is especially long or complex can be provided in manuals that employees can utilize as valuable reference tools. Manuals can also be used to house information that is utilized on a daily basis. For example, many organizations provide a directory listing the contact information of employees and other key personnel. Employees can then easily access contact information without having to memorize it or spend time tracking it down. Manuals can also include procedures for tasks that are not performed regularly and thus might not be memorized by employees. Electronic documents and databases are increasingly being used in place of paper manuals, as they are often more convenient to access and easy to update.

Organizations have also used manuals to aid the training process. On their first day of training, employees have traditionally been provided with a training manual that incorporates all the information that is relevant to their company and performing their job. Manuals have typically served as a supplement to classroom training that enabled trainees to learn the nuances and finer details of the job independently. The use of manuals as training aids has become less common, however, due to technological advances and the development of other learning strategies such as simulation and e-learning.

***Decision Support Systems***  As computers become increasingly integral to most work environments, classroom-based training programs continue to be replaced by computer-based platforms. Not surprisingly, computer-based job and training aids, such as decision support systems (DSS) and intelligent tutoring systems (ITSs), have also been developed to complement

such training programs and are rapidly replacing more traditional, paper-based aids.

Designed to improve and support human decision making (Brody et al., 2003), DSSs can be utilized both on the job and during training. When used as job aids, DSSs facilitate and improve decision making during actual task performance. The use of DSSs developed by the Navy, for example, led to increased confidence in decisions made and more effective performance during a decision-making task (Zachary et al., 1998). More recently, DSSs have been put forth as valuable tools for aiding in medical diagnoses (Lindgaard, et al., 2009) and response effectiveness in emergency situations (Yoon et al., 2008).

As training aids, DSSs are integrated into the overall training program, typically alongside simulations, and aid in the development of critical thinking and decision-making skills. DSSs are a valuable addition to scenario-based training exercises. During each simulation, the trainee can utilize the DSS during the decision-making process and receive feedback for each decision that is made. This strategy has been successfully implemented in the military in which DSSs provide real-time strategy training and feedback in a secure training environment (Bell, 2003). DSSs have also garnered support as effective aids in the training of emergency responses in the transportation industry (Yoon et al., 2008) and have even been proposed as a means of facilitating risky business decision-making training (Borrajo et al., 2010).

The ITS, a specific type of DSS, can also be used to facilitate training (Ong and Ramachandran, 2003). As training aids, ITSs can teach a variety of knowledge domains but are difficult to implement because they require extensive knowledge of the subject and strategies for error management. Examples and connections to relevant topics are also required to effectively aid the decision-making process. While ITSs require a great deal of time and effort to design and program, their potential benefits may outweigh the costs for some organizations. Training can be conducted without the physical presence of a facilitator and trainees can learn at their own pace, which can enhance the transfer of training. When used as job aids, the development of ITSs does not require extensive resources, as users should only need small amounts of specific information to supplement their existing knowledge of how to perform a task or reach a decision.

Job and training aids continue to be improved through advances in technology and the science of training. As the associated benefits of such aids increase and the costs required to implement them decrease, we will likely see more and more organizations incorporate them into their training programs. Utilizing job and training aids assists trainees in acquiring knowledge and skills and guides them when applying them on the job. Such tools greatly increase the likelihood that trained competencies will be transferred to the work environment.

### 9.3 Summary

The completion of training evaluation does not mark the end of the training process. Rather, organizations should work to establish a positive transfer climate and provide critical resources such as support systems, opportunities to perform, and job aids. If efforts are not made to facilitate the transfer of training, learned competencies will not be applied on the job, and the goals of the training program will ultimately not be met.

## 10  CONCLUSIONS

### 10.1  Future Directions

The science of training has expanded greatly over the past few decades; this is due largely in part to increasing levels of scientific rigor (Chen and Klimoski, 2007). Furthermore, the breakneck pace of technological advancements has both enabled and necessitated constant growth in the science of training. Two recent training fields likely to see much growth in the coming years are emotions and cognitive neuroscience.

***Emotion Regulation***   Recent research suggests that trainees' ability to regulate their own emotions may play a role in the training process. Emotion regulation generally refers to deliberate, effortful processes that serve to override individuals' spontaneous emotional responses (Koole, 2009). During such processes, people maintain, increase, or decrease positive and negative emotions, changing the way they experience and express their emotions (Gross, 1999). Emotion regulation has proven to have important implications for the workplace, particularly in relation to performance. The term emotional labor, for example, refers specifically to the management of individuals' emotions in the context of their jobs (Schaubroeck and Jones 2000). Engaging in emotional labor can have a negative impact on job performance (e.g., Duke et al., 2009). Recent findings suggest emotion regulation can also have implications for performance within training contexts. Specifically, several scholars have proposed that emotions are particularly relevant when training involves active learning or when trainees actively participate in the learning process, rather than passively absorbing information (Bell and Kozlowski, 2008). Being an active learner can be difficult and anxiety provoking; thus, it is important for trainees to be able to control their emotional reactions during training. Negative emotions can consume attentional resources, hindering learning and performance (Kanfer and Ackerman, 1989). This is particularly true during the early stages of training, when cognitive demands are at their highest.

Fortunately, strategies have been developed to help trainees regulate their emotions during training and alleviate the negative effects of anxiety on learning (Bell and Kozlowski, 2008). For example, instructing trainees to increase the frequency of positive thoughts and reduce the frequency of negative thoughts, along with positive reinforcement, can effectively reduce negative affect and improve performance during training (Kanfer and Ackerman, 1990). Further, work by Bell and Kozlowki (2008) suggests that emotion regulation interventions can reduce anxiety and help sustain trainees' motivation and performance in situations where trainees

| 3.  Person analysis | Identifies:<br>• Who needs training<br>• What they need to be trained on |
| | ***Training Design*** |
| 4.  Develop training objectives. | • Desired outcomes/goals are identified.<br>• Assumptions about training are identified.<br>• Objectives are documented.<br>• Competencies are established. |
| 5.  Consider individual characteristics. | Identifies trainee characteristics that may affect training:<br>• Cognitive ability<br>• Self-efficacy<br>• Goal orientation<br>• Motivation |
| 6.  Consider organizational characteristics. | Identifies organizational characteristics that may affect training:<br>• Organizational culture<br>• Policies and procedures<br>• Situational influences<br>• Prepractice conditions |
| 7.  Establish practice opportunities. | • Practice opportunities are specified (e.g., when they will occur during training, number of opportunities provided, levels of difficulty). |
| 8.  Establish feedback opportunities. | • Identifies when feedback will be provided (e.g., immediately after training) and at what level (e.g., individual, team, both) it is specified.<br>• Trainees know how they did.<br>• Trainees know where improvements are necessary. |
| 9.  Select an instructional strategy. | • The best instructional strategy or combination of strategies will be selected to train competencies of interest based on the needs of the organization (e.g., teams, technology, internationalization). |
| 10.  Outline the program content. | • Sequence and structure of the training program is laid out. |
| | ***Training Development*** |
| 11.  Develop practices scenarios. | • Realistic practice scenarios are scripted that engage trainees.<br>• Scenarios of varying difficulty are scripted. |
| 12.  Develop performance measures. | • The measurement plan is identified.<br>• Criteria for success are developed.<br>• Performance measures are established.<br>• Tools for assisting performance measurement are developed (e.g., observation checklists). |

**Table 8** (*continued*)

| Step | Outcome |
|------|---------|
| *Training Implementation* | |
| 13. Select the instructional setting/location. | • Available training site is identified.<br>• Training environment is prepared. |
| 14. Train instructors. | • Instructors are adequately trained to conduct the instruction.<br>• Instructors are knowledgeable in terms of the program content to handle questions and/or problems that may arise. |
| 15. Conduct a pilot test. | • Issues or concerns with training are identified.<br>• Feedback is received from trainees.<br>• Necessary adjustments are made to the training program. |
| 16. Conduct the instruction. | • Developed instructional materials are put into practice.<br>• Training program is live and functional.<br>• Training program is completed. |
| *Training Evaluation* | |
| 17. Consider evaluation design issues. | • Experimental plan is laid out (e.g., posttest only, control group vs. no control group).<br>• Where evaluations will be conducted is specified (i.e., in the field, on the job, both). |
| 18. Consider costs of training evaluations. | • Low-cost alternatives are explored (e.g., unequal sample sizes between trained and untrained groups; low-cost proxy criterion measure selected). |
| 19. Evaluate training system at multiple levels. | • Data on training's effectiveness are collected at multiple levels and analyzed.<br>• Data on job performance are collected and analyzed. |
| *Transfer of Training* | |
| 20. Establish a positive posttraining environment. | • Organization and supervisors support competencies on the job.<br>• Continuous learning climate is established.<br>• Trainees are rewarded.<br>• Behaviors that contradict those that are trained are discouraged. |
| 21. Use job aids. | • Performance on the job is enhanced. |

experience stress. These studies suggest that emotion regulation may be an important factor to consider both as a trainee characteristic and as an element of training design, particularly in very difficult or stressful training situations.

***Cognitive Neuroscience*** One arena of study that looks to be promising in relation to the science of training is neuroscience (Salas and Kozlowski, 2010). Neuroscience explores the circuitry of the brain; research in this area may help training designers gain a better understanding of how the brain (and by extension, learning) operates. Neuroergonomics is a subfield of neuroscience; it differs from neuroscience in that traditional neuroscience is interested purely in the functioning of the brain. To this end, cognitive neuroscientists utilize painstaking, and occasionally invasive, methods (e.g., functional magnetic resonance imaging and computerized tomography scan) in order to observe how the brain works. However, research has shown that brain activity differs by context (i.e., labs, simulations, or real world) (Parasuraman and Wilson, 2008). This presents a problem, however, if research in neuroscience is to be applied to the field; accordingly, neuroergonomics has emerged in recent years, examining the brain at work in field settings. Studying brain functioning in relation to human interaction with various

systems, be they technologies or training regimens can help product and training designers develop systems that are maximally suited to human performance (Parasuraman, 2009). At an even deeper level of analysis, molecular genetics allows researchers to link certain genes to specific cognitive functions (e.g., selective attention, working memory, vigilance). Furthermore, genetic makeup can be tracked to more complex brain activity, such as decision making (Parasuraman, 2009). Implications for training may be tailoring training methods to certain genotypes, among other things.

## 10.2 Summary

A strong, capable workforce is critical to the development and success of most organizations. In order to develop their employees' competencies and maintain a competitive advantage, organizations should place a heavy emphasis on training. The purpose of this chapter was to provide an updated training review and offer further guidance related to the design, delivery, and evaluation of training programs (see Table 8). We maintain our position encouraging training designers to take a systematic approach to the training process by carefully considering each component involved. Organizations have much to gain from utilizing the science of training that has been developed and refined by scientists and professionals spanning multiple fields.

# CHAPTER 18

# HUMAN FACTORS IN ORGANIZATIONAL DESIGN AND MANAGEMENT

**Pascale Carayon, Peter Hoonakker, and Michael J. Smith**
**University of Wisconsin–Madison**
**Madison, Wisconsin**

## 1 INTRODUCTION

As we write this chapter the world is starting a very slow recovery from the greatest economic recession since the 1930s. There is high unemployment, a lack of new jobs, low investment in businesses, and slow growth in developing countries. The demand for products and services is down. Companies are looking for ways to cut costs, reduce overhead, and right size. This puts pressure on management to cut budgets and staffing and to squeeze higher productivity and quality from all company resources, including capital, technology, and people. In such a demanding and difficult economic environment there is a tendency for companies to develop organizational design and management policies and practices that create negative corporate cultures for the people resources. At the same time there is increased emphasis on using new "technology" to bring substantial benefits for the economic prosperity of a company. This leads to devaluing the people resources and increases job stress, low motivation, and employee apathy.

In this chapter we will focus on how to build an organizational design and management culture and process that permits people to be highly motivated, productive, and effective and lets them have a high quality of working life and be safe. A central assumption of this approach is that meeting the expectations and needs of the people in an organization is necessary for both the short- and long-term economic success of the organization.

Consistent with many organizational design and management authors (Carayon and Smith, 2000; Deming, 1986; Hackman, 2002; Hendrick, 1986, 1987; Lawler, 1986, 2003; McGregor, 1960; Smith, 1965; Smith and Carayon-Sainfort, 1989; Smith and Carayon, 1995), we view employees as the foundation on which to build a successful sustainable and healthy organization.

As we proceed, we present our perspectives on organizational design, operations, and management. Our beliefs are grounded in theory, research, and practice, and that gives us confidence that these perspectives can be helpful to many organizations.

This chapter begins by providing some background context about the history of organizations and organizational design and management. We then discuss how this context provides a basis for a greater focus on the importance of finding meaning in work and life. We describe the key attributes of healthy and sustainable work organizations, organizations that are able to respond to the difficult circumstances of the current economic reality

and future growth. We then present the work system model and design principles and methods that provide more specific guidance on actions that can be taken to create a healthy and sustainable work organization.

## 2 BACKGROUND AND HISTORICAL PERSPECTIVE ON ODAM

The background in organizational design and management discussed here comes from the traditions in North American and Western European conceptualizations of organizations and how they operate. We recognize that there are many other traditions and concepts with rich histories and important knowledge. We believe that many of these other traditions provide reasonable alternatives to our approach. We have focused our approach to the societal, cultural, and management processes based on the behaviors of organizations and individuals in the regions of the world where we have our greatest knowledge and experience.

Organizational structure has always been a primary consideration in organizational design and management. Since the dawn of human history there have been various organizational structures for groups of people who have come together around common interests. Over time, the structures of these groups have increased in their complexity as the size of the organizations grew and as varied interests had to be accommodated. As organizations became more complex, they formed multiple sectors or departments of specialization. This mirrored the growing complexity of society with multiple sectors, such as government, military, judicial, religious, agricultural, marketplace, trading, financial, construction, artisan/professional, and labor. Work organizations developed a similar makeup, with management, finance, security, manufacturing, marketing, sales, customer services, transportation, and human resources. This complexity led to a need for structure, rules, and procedures to provide effective and efficient operations.

As Smith (1965) reported, very early in human history a dominant organizational structure, the hierarchy, was developed. One leader at the top had absolute power and then delegated authority and responsibility downward in a pyramid-type progression. The greatest power and authority were held by those few near the top, while little was present near the base. This is the well-known top-down power structure of an organization. Independent of the nature of the leadership, the structure of the organization typically followed a military structure with a top leader (CEO), generals (vice presidents), colonels (division managers), lieutenants (department managers), sergeants (supervisors), corporals (lead workers), and privates (employees), with orders flowing downward. To this day, this type of hierarchy and military style of command structure remains the dominant structure of small and large organizations. One addition of the few that have commonly been implemented is the "board of directors" at the top of the pyramid representing stockholders.

Characteristic of this structure is the chain of command, with the orders for action flowing from the top down through the organization to the bottom. Functions, knowledge, and skills tend to be specialized within specific units of the organization, sometimes referred to as divisions or departments. This structure requires the coordination and integration of expertise within and across the various units into a unified operation, and this is accomplished through the management process. At the higher levels in the hierarchy, the management functions are more similar than they are different, but specialized knowledge may still differentiate one unit from another. However, at the lowest level in the hierarchy, the activities of the people are quite different across departments, and front-line supervisors are well versed in the day-to-day details of how specific activities in their department are carried out with little knowledge of the specifics of other departments.

In the early twentieth century much emphasis was put on the specialization of function and knowledge at the department level, the supervisor level, and the individual employee level. The purpose was to develop greater expertise by focusing the attention and skills of the workforce to a limited number that could be mastered. To build competence and skill, researchers and practitioners used scientific measurement methods and motivational theory to improve employee performance and productivity substantially. This led to highly structured work activities that required focused knowledge and intelligence and highly developed perceptual–motor skills. The workforce responded positively to the specialization of function. People learned new skills and took pride in the quality of what they produced, and their wages and standard of living increased substantially.

Over the next several decades the workforce became more educated and less satisfied with the narrowly focused and specialized nature of their work, which led to routine, boring work and the realization that opportunities for growth were limited. This led to problems in productivity and serious concerns for employee physical and mental health. New organizational structures and approaches to job design were developed in the early part of the twentieth century but became more widespread in the middle of the twentieth century and progressed through the rest of the century (Black and Porter, 2000; Lawler, 1986, 1996, 2003; Parker and Wall, 1998; Porter et al., 2002). However, even with the growth of new management approaches and job designs, the most dominant organizational approach in the United States and Western Europe remained a hierarchical militarylike structure with top-down power, authority, and decision making. This structure was difficult to discard because it was effective in getting the orders followed, departments coordinated, and products and services produced and delivered in a consistent manner.

Some of the important lessons that we believe emerged from studying the organization and management of work over the past 100 years are that (1) the hierarchy structure of management and control produces predictable results; (2) an effective hierarchy structure does best when there is a top-down power structure with a strong leader; (3) other forms of organizational structure can be effective, but primarily in

small organizations or in large organizations that operate as an integrated network of small businesses or in environments with high uncertainty; (4) people at all levels of the hierarchy are critical resources to the success of the organization; and (5) the best organizational designs incorporate the needs and the knowledge of the workforce in managing the organization.

Starting around the beginning of the twentieth century and up to today, much has been learned about how organizational structure and management affect employee satisfaction and performance. Early on we learned that employees responded well to taking orders from supervisors if they trusted the orders (McGregor, 1960; Smith, 1965; Taylor, 1911). They followed explicit instructions in what tasks to do and the directions and specifications about how to do the tasks. This created clear roles and responsibilities for managers and employees, removed role ambiguity, and let employees explicitly know their performance requirements. Employees responded positively to efforts to improve their skills through training and education. They appreciated new tools and technology that reduced the effort needed to do their tasks and increased the rewards that came with high achievement. The application of detailed and careful evaluation of work management, operations, and tasks led to a "scientific" basis for establishing guidelines for employee selection, supervision, the design of work tasks, and performance requirements (Drucker, 2001; McGregor, 1960; Smith, 1965; Taylor, 1911).

The consistent use of scientific work evaluation and design methods was well received by employees when the methods were perceived as unbiased and fair. This established some important human factors considerations in organizational management that led to increased employee satisfaction with their work and less stress. Human factors considerations included developing reasonable and fair work standards and creating an environment in which employees would trust the organization's decisions and feel they were treated fairly.

For the fair treatment of employees and their perceptions of fairness and trust, "scientific" analytical methods and design criteria were used as the basis for work design and management. These scientific methods and criteria were based on sound evidence of validity and reliability and were simple and clear enough to be understood and accepted by the employees. When such "fair," "trustworthy," and "scientific" requirements were applied to managing and designing work, the employees were more satisfied and less stressed and performed better than when arbitrary requirements were applied (Carayon and Smith, 2000; Lawler, 1996, 2003; Smith, 1965, 1987).

Although the formal structure of the organization and the management process are important for organizational success, we have learned that the informal and social aspects also need to be considered since they can influence the effectiveness of the formal elements (Lawler, 1986; Roethlisberger and Dickson, 1942). The informal hierarchy of leadership and management that exists in work organizations can substantially influence the attitudes and behaviors of employees. Social

processes at work can influence cohesiveness within the work unit and how close employees feel toward the organization. Both of these factors can influence employee satisfaction, stress, and productivity. Informal leaders can facilitate management of the organization by their conformity with formal directives or can inhibit organizational management by presenting contrary perspectives and directives to employees. The informal influence can be so subtle that it does not appear to confront management directives directly. Informal influences can also provide assistance to employees in obstructing the goals of management. In organizations that have labor unions, the informal processes tend to be organized and are easier to identify, and it is easier to understand their perspectives. The work group can buffer stressful aspects of work by providing social support and technical assistance to co-workers (Caplan et al., 1975; French, 1963; House, 1981).

To take advantage of the social aspects of work, many companies use special programs or processes to get employees more involved in the improvement of products and the company. For example, they use quality circles and other techniques of total quality improvement to get employees involved in the design of their own work (Carayon et al., 1999; Deming, 1986; Lawler, 1986; Smith and Carayon-Sainfort, 1989). Some companies use climate questionnaires to assess the status of employee satisfaction and stress and to define specific areas of employee concern (Lawler, 1986). These approaches provide data to help management align formal and informal structures. Successful organizations recognize the importance of aligning the formal management process with informal social processes to get employees positively involved in organizational success. An important human factors consideration is for companies to recognize the importance of the informal social aspects of work groups and to provide formal structures and processes that harness the informal group process to benefit the management of the organization and the satisfaction and success of the employees.

The power of the social process in organizations has been recognized and is one of the drivers in the shift from individually based work to using groups, or teams, of employees working together to achieve a goal (Hackman, 2002; Sainfort et al., 2001; Salas et al., 2004). Although it is commonly recognized that many complex issues require a cross-functional team-based approach, teams have also been found to be beneficial for other reasons in jobs that were previously done in isolation or on assembly lines. By creating work teams, an environment that provides social support can be fostered. Social support has been shown to reduce stress for employees (House, 1981). Team-based work processes are observed in a wide variety of organizations, from manufacturing production and assembly processes to service activities and in new product or service design processes (Sundstrom et al., 1990). Companies teach employees about the importance of teamwork, how to interact in a team, and how to coordinate with other teams.

Teams consisting of managers, marketing, sales, engineering, production, and labor are used to solve

critical product design problems and develop new products. When team operations can be achieved for making products, assembling products, providing services, and selling, they provide social and motivational benefits that lead to greater employee satisfaction and performance (Sainfort et al., 2001). However, social pressures from the group can sometimes increase employee stress, and this requires careful monitoring by the organization. Many management approaches call for the inclusion of front-line employees as part of a team formed to resolve product and service quality problems. Teams capitalize on the mixing of perspectives and knowledge to define problems and to develop preferred solutions. Teams capitalize on multiple domains of expertise, and they also capitalize on the social aspects of the process that provide positive feelings of recognition and respect to the individual participants.

An important consideration in managing work is that employees like opportunities to participate in the decision-making process (Haims and Carayon, 1998; Lawler, 1986; McGregor, 1960; Noro and Imada, 1991; Sainfort et al., 2001; Smith and Carayon-Sainfort, 1989; Wilson and Haines, 1997). Employees like to feel important, respected, and appreciated. Positive participation experiences address an employee's social and ego needs. Organizational management processes that incorporate employee participation into production, problem-solving, designing, and/or opinion-sharing activities provide benefits to both the organization and the individual employee (Wilson and Haines, 1997).

## 3 HEALTHY AND PRODUCTIVE ORGANIZATIONS

### 3.1 Historical Perspective

Since the time of Frederick Taylor's principles of scientific management of work and Henry Ford's application of the assembly line to increase production there have been competing approaches to managing the design of work and the management of the workplace. Taylor and Ford emphasized the simplification of tasks, the use of better tools and technology, and close supervision of workers to achieve substantial gains in worker productivity. They were very successful and established a template for work design and management that is still used by many companies around the world a century later. Workers benefitted through higher wages and/or pay incentives for high performance. But there was dissatisfaction with the simplified nature of the tasks and the high-performance demands placed on workers. As unionization of industries spread in the United States in the early to mid-1900s, worker resistance to these approaches increased and social reformers decried the "dehumanization" of work. Psychologists, sociologists, and management theorists began to appreciate work as an important aspect of a person's life that provided more than economic maintenance. Work was associated with self-esteem, peer esteem, social status, and aspects of life accomplishment and satisfaction.

The counter approach to scientific management came from theorists and applied management experts in Europe and the United States. They saw work as a social and psychological process that could be managed to benefit the enterprise as well as the individual worker. The Hawthorne Studies of the 1920s and 1930s brought attention to the importance of group processes, peer pressure, and peer support on worker performance independent of the quality of physical working conditions. The importance of group affiliation, informal group influences, group leadership, and supervision style on worker behavior and performance became apparent. The idea that people worked for more than economic reasons came forward. The need for "affiliation," "meaningful" work, and "recognition" was embraced. The "intrinsic" aspects of work became as important as the "extrinsic" aspects (Herzberg, 1974). There was a belief that workers would excel when given greater autonomy over their work and embrace the opportunity to perform at high levels. The human side of enterprise and human relations at the workplace became a counterbalance to scientific management.

The theories and approaches of Taylor and Ford were opposed by the theories and approaches that proposed "humanizing" work. Over the many intervening decades since the 1920s the underlying beliefs and principles of each of these varying approaches have been debated, studied, competed, and revived in many forms under different names and methods. The basics of the "scientific management" approach have retained the use of measurements and quantification, improved technology, and financial incentives to achieve improvement in worker performance. The basics of the "humanistic" approach have relied on social and psychological processes to achieve improvements in the quality of working life and worker performance.

Concurrent with the development of the humanistic approaches to work design there was a close examination of worker safety and health. Governments implemented laws and regulations to protect the safety and health of workers. As part of this movement there was an interest in how the design of work affected the mental and physical health of workers. Hans Selye's (1950) landmark work on a generalized "stress" syndrome led to interest in how the physical, psychological, and social aspects of work interacted to affect workers' physical and mental health. In addition, an emphasis was put on the "ergonomic" characteristics of work in terms of how job demands affected workers' injuries and illnesses. Aspects of Taylor's approach to work measurement and task analysis and the humanistic approaches to work design started to come together. Integrated theories of the design and management of work were developed, including participatory ergonomics and macroergonomics. These integrated theories encompassed aspects of work measurement, efficiency, productivity, quality, quality of working life, job demands, physical and psychosocial stress management, and worker safety and health into a complete package for designing and managing the workplace. At the heart of the integrated organizational design and management (ODAM) approaches was the concept that happy, satisfied, unstressed workers will be healthy and productive workers. Healthy and productive workers lead to a

healthy and productive enterprise. However, the belief that happy workers are productive workers has been debated for decades and continues to be debated.

## 3.2  Happy, Healthy, and Productive Workers

Since the 1920s many theorists and applied management experts have proposed approaches to achieve happy, satisfied, and productive employees. While there have been differences in content and emphasis in these approaches the basics have remained consistent. Jobs that provide workers with autonomy, control over aspects of work tasks, reasonable physical and psychological demands, and employment security will lead to higher employee satisfaction with work and lower job stress. Such employees will be more productive in terms of the quantity and quality of products, services, customer satisfaction, and developing new ideas and products. These employees will have greater commitment to the enterprise and lower intention to turn over.

In 1975 the U.S. National Academy of Sciences asked a group of scholars to examine the issues of improved quality of working life and productivity at the workplace. Two important articles on improving productivity and job satisfaction/quality of working life were produced. The first, by Katzell et al. (1975), concluded that job satisfaction and productivity do not follow parallel paths. Therefore it did not follow that simply increasing job satisfaction would necessarily lead to greater productivity. They believed that the objective of increasing both job satisfaction and productivity were not incompatible and could be met. But it was not sufficient to increase worker satisfaction and expect greater productivity because the two constructs were only loosely coupled. An array of methods for improving job satisfaction such as job enrichment, management by objectives, autonomous work groups, and participative management, when implemented by themselves, were more likely than not to leave productivity unchanged or at best to improve it marginally.

These approaches could even lead to reductions in productivity by the disruption of ongoing work processes. These scholars concluded that no one approach was sufficient to simultaneously affect both productivity and employee satisfaction significantly. They stated that two barriers limited the potential for increasing job satisfaction to benefit productivity. The first was "resistance to change" and the second was the insistence on focusing on just "one" approach versus using a variety of methods.

Katzell et al. (1975) proposed five concepts that they felt were supported by their examination of the literature to support both increased job satisfaction and productivity improvements:

1. *Critical-Mass Principle.* Organizational changes required to achieve changes in job satisfaction and productivity have to be sufficiently deep and far reaching to make substantial effects and not just transitory effects. The change does not have to be made all at once and can be staged. Changes in job satisfaction and productivity should not be expected until at least several stages have been undertaken.

2. *Motivation Principle.* The elements of the stages need to be integrated around the concept of developing satisfied *and* highly motivated workers. High job satisfaction is not sufficient for high performance. High motivation to perform needs to be tied to high satisfaction. Effective worker performance should be rewarded in whatever terms are meaningful to the individual, be it financial, psychological, or both. The idea is to develop workers who are "committed" to high performance because of a reward structure that leads to high job satisfaction and high productivity.

3. *Shared Benefits.* An extension of the motivational principle is that workers at *all* levels of the organization must see that the organizational changes will benefit them in terms that are important to them.

4. *Job Design.* Changes in job content need to be substantial enough to be perceptible to workers and typically include greater self-regulation, diversity in tasks, meaningfulness, challenge, and social responsibility. In addition, changes in job content need to be part of a larger program of improved policies and practices that has aspects of adequate pay, job security, proper resources, working conditions, increased mutual influence at all levels, and constructive labor–management relations.

5. *Pattern of Control.* There are three levels at which a redistribution of influence and control in organizations are important: the individual job, the work group, and the organization. Increased autonomy or self-regulation is key to increased job satisfaction and productivity for some workers but not all. Providing workers with a voice over what goes on in their work group has been shown to have favorable effects on satisfaction, work motivation, and turnover. Organizations in which members at all levels exercise greater control over what goes on in the organization typically are more productive and have more highly motivated and satisfied workers.

6. *Patterns of Compensation.* Workers who are more highly paid generally like their pay and their jobs better and are less likely to quit or be absent. Workers in a given job who are paid more than other workers with a comparable job are also likely to have higher motivation and productivity, but only if their pay level is linked to their performance.

7. *Systemwide Changes.* Studies have shown that large-scale systemwide organizational changes had greater benefits for productivity and job satisfaction increases. These extensive changes create a "new" work system.

Katzell and colleagues (1975) concluded their evaluation of the organizational change literature findings and

conclusions with six principles for potential success in increasing worker job satisfaction and productivity:

1. The pay of workers must be linked to their performance and productivity gains.
2. Workers and jobs must be matched to meet their capabilities, needs, and expectations and provide the resources for them to succeed.
3. Jobs should provide the opportunities for workers to use their abilities, make meaningful contributions, challenge, diversity of duties, and being responsible for others, but only for those workers who desire these factors.
4. Workers at all levels should have input to plans and decisions affecting their jobs and working lives.
5. Necessary resources must be provided for achievement of high performance.
6. Adequate "hygiene" conditions such as competent supervision, fair pay and fringe benefits, job security, good working conditions, and sound employee relations must exist.

The second paper, by Cummings et al. (1975), examined how to improve the quality of working life and worker productivity. It also examined an extensive literature dealing with job satisfaction, productivity, and organizational design. Their paper looked at three main types of knowledge from the literature for developing effective strategies for improving productivity and worker satisfaction: "action levers," contingencies, and change strategies.

Action levers were seen as the first step in improving working conditions that could be manipulated to create desired changes. The action levers were:

1. Pay/reward systems for performance
2. Autonomy/discretion for workers
3. Support services from technical groups
4. Training of all workers for all jobs in a department
5. Flat organizational structure
6. Rearrangement of the physical plant
7. Task variety
8. Information and feedback from users
9. Increased interpersonal interaction in groups/departments.

Cummings and colleagues (1975) concluded that the literature supported the belief that manipulation of these action levers produced positive outcomes in cost reduction, increased productivity, lower rates of rejected products, decreased employee turnover and absenteeism, and increased job satisfaction. They classified the general approaches to organizational redesign into four categories: (1) sociotechnical/autonomous work groups, (2) job restructuring such as job enrichment, job enlargement and job rotation, (3) participative management, and

(4) structural changes at the organizational level rather than the job or departmental levels.

Cummings et al. (1975) indicated that contingencies were factors that affected the success of the action levers. Action levers were manipulated in situations with human and organizational peculiarities, and these contextual differences needed to be taken into account in any change effort. Their review of the research literature led to the conclusion that the manipulation of the action levers was more likely to produce positive outcomes when the contingencies were used. The contingencies included:

1. Support for the changes from the highest involved level of the organization
2. Addressing worker "higher order" needs
3. Pay and reward systems based on a group rather than an individual basis
4. A technological process that allows for relatively self-contained task groupings
5. An adequate training program for establishing technical skills
6. Recognition that workers are capable of assuming responsibility for a "whole" task
7. First-level supervisors supportive of the changes
8. Changes that deal with abilities valued by workers
9. Changes that do not adversely impact interpersonal relationships
10. Increased participation that is seen as a legitimate part of work
11. No strong resistance to the methods of introducing participation
12. Participation that involves decisions that workers perceive as important
13. Workers possessing a need for independence
14. Participative decisions that motivate a worker to enter and remain in the organization
15. Organizational "climate" that is supportive of innovative behavior
16. High level of trust between workers and managers

Cummings et al. (1975) proposed key aspects of organizational redesign strategies taken from their evaluation of the literature:

1. Pick one of the four strategies (identified above) that fits your organization, but be flexible and incorporate elements of the other three when appropriate.
2. Department- and group-level changes have shorter time scales and smaller impact than systemwide strategies. There will be ripple effects when change occurs, and these must be accommodated for successful implementation. Unanticipated consequences are the rule, not the exception.

3. Decide whether to involve the target group actively in the change process decision making. Even though participation is a central aspect of the change process, there are situations when worker involvement in decisions will be disrupting.

4. Make the first steps in the change process small and adopt an evolutionary approach. Be flexible as the process evolves using data on successes and failures to direct future directions. Start with pilot projects and then widen the scope of the change process.

5. Build information-gathering processes into the change process.

6. Be opportunistic. Take advantage of situations that arise which provide new insights, opportunities, and chances to make gains.

7. Avoid the trap of having to prove the success of the innovations. Think long term and look to the "big picture." Do not focus on small successes or failures, and do not pressure managers over short-term failures. Managers need flexibility to adapt to the unanticipated consequences of changes.

In 1970 the U.S. National Institute for Occupational Safety and Health (NIOSH) undertook a program to define workplace factors that related to employee job stress. It is interesting that this effort had some parallels to the work of the U.S. National Academy of Sciences to examine work organization and productivity. The NIOSH program was looking at characteristics of work organization and work design with an emphasis on worker mental and physical health rather than job satisfaction and quality of working life. One of the first major studies from this program was completed in 1975 at the same time the National Academy of Sciences work design and productivity findings were coming out (Caplan et al., 1975). This study collected questionnaire responses about working conditions, job satisfaction, and health from 2010 employees in 23 occupations. The study established relationships among workers' perceptions of job stressors and behavioral, psychological, and somatic outcomes. An important finding was that the occupations that had more task complexity, higher levels of participation, and lower levels of underutilization of abilities were the most satisfied with their jobs.

Cooper and Marshall (1976) categorized sources of job stress into five categories: (1) factors intrinsic to the job such as demands and dangers, (2) factors that affect a person's role such as role ambiguity and role conflicts, (3) career factors such as promotion and job security, (4) relationships with others at work, and (5) organizational climate issues such as participation. They conducted a comprehensive literature review and concluded that job stressors led to worker stress and recurrent worker stress can lead to chronic disease.

Frankenhaeuser and Gardell (1976) and Gardell (1981a, 1981b) declared that there was an epidemic of stress due to "Taylorization" of work. Further they claimed that "psychosocial" aspects of work defined the "happiness" with work and the level of job stress. In Scandinavia and Western Europe there was a strong movement to promote worker involvement and participation in the design of work to humanize working life. Karasek (1979) found that workers in jobs with high work demands and low decision latitude had an increased risk for coronary heart disease.

What is intriguing about the happy, satisfied, productive worker literature and the job stress literature of the 1970s is that these different approaches to examining work both found that similar aspects of work design and organizational design, management, and culture were associated with better worker productivity and lesser job stress and strain. These aspects of work included matching job content to workers' expectations, skills, and capacity; providing variety in tasks; involving workers in decision making and giving workers control over tasks; providing job growth and security; promoting social support; rewarding good performance; and supportive supervision and management. These job and organizational characteristics led to a "culture" in which both workers and companies benefited.

### 3.3 Recent Perspectives on Happy, Productive Workers and Workplaces

More recent theoretical discussions and research promote and support the idea of happy, healthy, and productive work, and they bring these ideas into a contemporary context. Harter et al. (2002) proposed that worker well-being was in the best interests of communities and organizations. In particular, organizations spend substantial resources in developing human resources in efforts to generate profits and customer loyalty. Harter et al. (2002) carried out an extensive review of the literature examining work, life satisfaction, job satisfaction, health outcomes, and business outcomes. Generally, they found that working conditions affected worker health, stress, and satisfaction and individual employee satisfaction was related to job performance. The happy–productive worker concept was linked to emotional well-being and work performance. In conclusion, they stated that work was a pervasive and influential part of the individual's and community's well-being. It affected the individual's quality of life and mental health and thereby could affect the productivity of entire communities. The organization's ability to promote worker well-being rather than strains and poor emotional health was a benefit to the worker but also a benefit to an organization's bottom line.

Harter et al. (2002) proposed six characteristics of jobs to promote employee well-being and productivity:

1. Basic materials and equipment to carry out the job tasks

2. Role clarity and expectations

3. Feelings of contributing to the organization

4. Sense of belonging

5. Opportunities for growth

6. Chances to discuss personal progress

Wright and Cropanzano (2004) took a "fresh look" at the role of psychological well-being and job performance by taking a "positivist" position on the influences of work and life experiences. Their review of past research concluded that high levels of worker psychological well-being (emotional well-being) led to increased job performance and an increased capacity to appreciate new opportunities and experiences. They indicated that employee-focused, positive psychological-based interventions at work take three general forms:

1. *Composition of Workforce: Worker Selection.* Research has shown that worker psychological well-being and happiness were stable over long periods of time as long as five years. This may provide a possibility of using selection procedures that try to determine the current "happiness" and/or psychological well-being of job applicants. However, they pointed out that selecting the happiest job applicants as workers raises the specter of potentially serious ethical issues.

2. *Training Workforce.* A second option is to train workers in methods to be happier. For example, stress management training can have positive effects on worker happiness. Another strategy is training workers in strategies to change their personal perceptions from negative to positive. Constructive self-talk and other approaches to cognitive restructuring are examples of this. Still another strategy is training workers in "learned optimism," a method emphasizing positive thought patterns. Research has shown that optimistic workers perform more effectively in a wide range of occupations, especially those that require significant interaction with others.

3. *Situational Engineering of Workplace.* This approach requires changing the work environment so that it promotes worker psychological well-being. There is evidence that working conditions strongly affect worker psychological well-being. For example, reengineering the work environment such as the physical, social, work role, task, and job demands has been shown to be related to worker emotions. Family, friendly organizational policies such as flex-time and childcare programs should increase worker psychological well-being.

Quick and Quick (2004) emphasized that it was useful to consider "public health" ideas to manage the health and well-being of the workforce to achieve happy, healthy, and productive workers. From the five principles that they used to develop a "preventive stress management" framework, two were central to managing organizations to achieve worker health and productivity:

1. *Individual health and organizational health are interdependent.* Workers who are unhappy and stressed can drain positive energy that otherwise could be put to use to achieve happiness and productivity. Poor working conditions that lead to psychosocial stress produce "emotional toxins" that undercut motivation, health, and happiness.

2. *Leaders have a responsibility for individual and organizational health.* Leaders can use the tenants of "positive psychology" to promote a healthy and productive workforce. Positive psychology aims to build on an individual's strengths and competencies to promote health, well-being, and effectiveness. When leaders apply the tenants of positive psychology to the entire workforce, then they can develop the workforce into a happy, effective, and productive engine of the organization. Leaders should focus on keeping the workforce and themselves healthy, happy, and productive in the service of the organization.

Quick and Quick (2004) indicated that an emphasis on individual and corporate health was based on having happy, healthy, and effective workers and managers. Leaders and organizations that develop the skills and competencies of workers and managers can optimize the contributions that can be made to productivity and in the process produce healthy and happy workers. As with public health approaches, this approach emphasized preventive programs to keep the workforce healthy, happy, and productive. Such preventive programs were grounded in developing the capabilities of the workforce, eliminating the conditions that diminished worker competency, and designing work that led to workers who were happy and effective.

These concepts are parallel to the older ideas about enhancing worker job satisfaction, designing jobs that reduce stress, and making work meaningful, which will lead to effective and motivated workers that are highly productive.

Grawitch et al. (2006) reviewed the literature about healthy workplaces, employee well-being, and organizational improvements. They identified five workplace practices that had direct and indirect links between healthy workplace practices and organizational improvements:

1. *Providing Work and Life Balance.* Conflicts between work and family life diminish an employee's perceptions of the quality of each. The structure of work has a strong influence on family life; for example, work schedule affects the time available to interact with the family. Work–family conflicts have been tied to increased absenteeism, while corporate work–life balance programs have been tied to worker's organizational commitment and job satisfaction. Family–life balance features such as flex-time and fringe benefits may build employee loyalty and morale.

2. *Employee Growth and Development.* The opportunity to gain additional skills, knowledge, and experiences can act as motivators which can

translate into positive gains for the organiza-
tion. Training and internal career opportunities
have been shown to be significant predictors of
organizational effectiveness and job satisfaction.
Training opportunities were related to less job
stress. The effectiveness of training programs
was enhanced when workers were able to apply
what they learned to their jobs.

3. *Health and Safety.* Implementation of healthy
   workplace and safety initiatives can be seen as
   a form of organizational support of the workers.
   Research has found that high levels of worker
   stress led to higher health care expenditures and
   greater absenteeism. Health promotion programs
   led to lower absenteeism and lower health care
   costs. Stress management programs have been
   shown to decrease absenteeism and increase
   productivity.

4. *Recognition.* Employee recognition has been
   found to be a significant predictor of organiza-
   tional effectiveness, worker job satisfaction, and
   worker stress. In particular, worker compensa-
   tion was critical to a healthy workplace. Com-
   pensation and fringe benefits attract and retain
   workers.

5. *Employee Involvement.* Employee involvement
   has been related to worker satisfaction and
   morale and to lower turnover and absentee-
   ism and higher quality of work/products. Em-
   ployee involvement programs led to benefits for
   workers and for the organization.

These five organizational practices are in line with
the earlier proposals dealing with happy, satisfied, and
productive workers.

### 3.4 Recent Research on Worker Happiness, Attitude, and Productivity

Taris and Schreurs (2009) studied 66 Dutch home health
care organizations to examine the relationship among
workers' emotional health and job satisfaction and
client satisfaction and organizational productivity. Three
separate studies were undertaken: a questionnaire survey
of the organizations' workers, a questionnaire survey of
the organizations' clients, and an accounting study of
the financial condition of the participating organizations.
In the first study responses to the survey on quality of
working life were received from 56,963 workers (48.7%
response rate) in 81 organizations. A second survey
of client satisfaction with services of the organizations
was undertaken almost simultaneously with the first
study. There were 54,987 respondents (51.5% response
rate). The health care organizations were asked to
voluntarily participate in an accounting evaluation of
their financial position. The analysis was carried out by
an international accounting firm. The data were collected
for the same time period as the employee and client
surveys. Overall there were data from all three surveys
from 66 organizations.

The employee survey examined job demands, job con-
trol, social support, emotional exhaustion, and employee
job satisfaction. The client survey examined 14 aspects
of the services received. The financial survey defined
organizational productivity as the number of service
hours delivered as a percentage of the total number of
hours produced by the employees of an organization.
This accounted for overhead differences in the orga-
nizations. In addition, personnel costs per hour were
calculated. Lastly, organizational efficiency was com-
puted based on the costs of one service hour. Then
the cost of one service hour was compared using a
method that benchmarked the cheapest cost as 100%
efficient and related all of the other organizations stan-
dardized to the benchmark. Multiple regression using
blocks of variables to define employee well-being (sat-
isfaction and emotional exhaustion), job characteristics
(demands, control, social support), organizational pro-
ductivity, personnel costs per hour, organizational effi-
ciency, and client satisfaction with services was used to
test relationships.

The findings indicated that employee well-being was
related to client satisfaction with services, organizational
productivity, and personnel costs per hour but not to
organizational efficiency. Job characteristics were not
significantly related to any of the financial indicators or
client satisfaction with services. Employee satisfaction
was positively related to client satisfaction with services
but negatively related to organizational productivity.
Employee emotional exhaustion was positively related
to personnel costs (higher costs) but was negatively
related to client satisfaction (less client satisfaction) and
productivity (less productivity). Emotional exhaustion
was positively related to job demands and control
(higher emotional exhaustion with higher job demands
and control) and negatively related to social support
(higher emotional exhaustion with lower social support).
The results indicated that, the greater the job demands,
the lower the job satisfaction, but the higher the social
support and job control, the greater the job satisfaction.
Generally the results of this large-scale study indicated
that worker emotional well-being in particular and
job satisfaction in some instances had benefits for
client satisfaction with services and financial benefits
for the organization. The happy worker was a more
productive worker.

Fisher et al. (2010) examined employee attitudes,
behaviors, and business performance in a multinational
hotel chain with operations in 50 countries. A ques-
tionnaire survey was used to collect information from
employees in the hotels in Mexico and China as part of
an annual employee survey process. The survey covered
employee demographics, attitudes, and behaviors [role
congruence, communication, leadership, commitment,
job satisfaction, and organizational citizenship behav-
ior (OCB)]. There were 3606 respondents from Mexico
(from four hotels) and 7896 respondents from China
(from four hotels) for an overall employee response rate
of 39.6%. Performance for each hotel was determined by
measures of percentage of annual house profits, revenue
per available room, and guest satisfaction ratings.

The hotels in Mexico were much more profitable
than the hotels in China and had higher scores for
guest satisfaction. There were significant differences

in employee job satisfaction, organizational commitment, and organizational citizenship behavior between employees in Mexico and China with the Mexican employees being higher on all measures. Nonparametric analyses (Spearman's rho) were used to test the relationships among job satisfaction and the financial measures and guest satisfaction. The results showed positive relationships between job satisfaction and the financial measures, but not with guest satisfaction. The same findings were found for organizational commitment. Organizational citizenship behavior was positively related to annual profit but nothing else.

## 3.5 So What?

The evidence from several decades of research indicates that there is support for the belief that happy, satisfied, unstressed workers are more productive, have fewer absences, and are less likely to leave the company; all of these positive impacts on workers benefit the bottom line of an organization in Western cultures. There has been much debate about the truth and/or strength of this relationship, and the debate will continue. With the current worldwide high levels of unemployment there appears to be little incentive for organizations to worry about whether their employees are happy, satisfied, or emotionally well. There is a deep well of job applicants that organizations can draw from to find

replacements for unsatisfied and/or stressed employees. On the other hand, the public health literature indicates that health care costs continue to go up at shocking annual percentage rates in Western countries. This is a significant cost to businesses and to countries that affects commerce, competitiveness, and the long term well-being of countries, companies, and employees.

Smart companies will understand that it is good business to have happy, healthy, and productive employees that offer high-quality goods and services to customers. This makes for a healthy and productive organization.

The next question is, "What can an organization do to be healthy and productive?" Based on a variety of theoretical perspectives and research findings over more than 80 years of research, case studies, and experience, some basic considerations can be reasonably suggested. See Table 1 for a summary of the principles for healthy and productive organizations.

## 4 HEALTHY AND SUSTAINABLE ORGANIZATIONS

In the previous section we presented a description of the attributes of a healthy organization. By a healthy organization we mean that the organization supports people's needs to find meaning, balance, authenticity,

**Table 1 Principles of Healthy and Productive Organizations**

| Principle | Description |
|---|---|
| Importance of human resources | Organizations should treat their human resources at least as well as their other resources (capital, structures, equipment, materials and supplies, products and services, inventories, and customers). |
| Relationship between employee well-being and health and organizational health | Organizations should recognize that the well-being of their workers affects the well-being of their enterprises. |
| Enhancement of work motivation | Organizations should make work (jobs, facilities, supervision, policies) an activity that workers are motivated to engage in effectively and productively. Make jobs such that workers look forward to going to work. |
| Need for continuous assessment and improvement | There are many organizational cultures and management styles that will promote worker well-being and satisfaction. Organizations should monitor the attitudes of workers regularly and make changes in their organizational culture and/or management style and/or job designs as necessary to achieve acceptable levels of worker well-being and satisfaction. |
| Importance of work–family balance | Organizations should remember that work affects almost all aspects of life. It is to an organization's benefit to provide policies and programs to help workers achieve a good work–life balance. |
| Relationship between well-being and productivity | Workers with high emotional well-being will be more productive and less likely to turn over. <br><br> 1. Workers who have economic security (reasonable pay, benefits, job security) will be less stressed and more satisfied. <br> 2. Workers with involvement at the workplace and control over task decisions will be less stressed and more satisfied. <br> 3. Workers with reasonable job demands will be less stressed and more satisfied. <br> 4. Workers who receive social support from peers and supervisors will be less stressed and more satisfied. |
| Importance of trust, respect, and fairness | Organizations need to engage in activities that develop trust, respect and fairness among workers, supervisors, and management. |

and spiritual fulfillment in work and life. Employee burnout is not good for an employee or an organization (Kalimo et al., 1997; Maslach et al., 2001; Smith, 1987), and people need to lead lives they can sustain in the long run if they are to be mentally and physically healthy. A healthy environment engages people's minds and hearts in meeting the needs of the organization. An organization cannot be sustainable unless it fully engages employees and their communities. It follows that a healthy environment is a prerequisite to a sustainable organization.

### 4.1 From Healthy Organizations to Sustainable Organizations

The term *sustainability* became widely known through the publication of *Our Common Future*, also known as the Brundtland Report, from the United Nations World Commission on Environment and Development (WCED, 1987). In the Brundtland Report (p. 24) sustainability is defined as "Development that meets the need of the present without compromising the ability of future generations to meet their own needs." Designing a healthy organization typically involves focusing on internal working conditions (see Table 1 and previous section) whereas designing a sustainable organization requires an additional focus on the environment in which the organization functions, in particular its social environment and the community at large (Delios, 2010; Pfeffer, 2010). This approach to healthy and sustainable organizations fits with the two (unfortunately distinct) approaches proposed by management researchers on business innovation and growth. Ahlstrom (2010) argues that the main objective of business is to develop new and innovative products and services. Disruptive technological innovations can lead to the development of new products and contribute to business growth. According to Ahlstrom (2010), it is through this innovation process that businesses can serve society by creating jobs, generating revenues, and allowing people greater access to cheaper products. This approach requires businesses to focus on their internal conditions and work organization in order to create opportunities for disruptive innovations and to foster entrepreneurial initiatives. This highlights the need for organizations to provide a good working environment for enhancing productivity and fostering innovation. Delios (2010) criticizes the approach proposed by Ahlstrom (2010) because it "ignores the external environment forces on an organization and it ignores the fact that organizations are social entities, populated by real communities of people" (p. 25). He proposes a broader view of business competitiveness that encompasses the issue of corporate social responsibility and the relationship between organizations and their larger social environment. In contrast to the strict transactional view of the relationship between people and businesses (such as Ahlstrom's (2010) approach), we need to understand the larger social role of business organizations. The transactional view focuses on the work that individuals perform in organizations. This is an important element of organizational design and management (see previous section); however, this is insufficient. The relationships between

employees and organizations have become more complex; often organizations play a central role in employees' lives and the communities in which employees live. Therefore, a comprehensive human factors approach to organizational design and management needs to include a focus on both internal organizational conditions for healthy and productive organizations and external conditions for sustainable organizations.

The World Health Organization (WHO) has adopted a similar broad approach to healthy workplaces (WHO, 2010). A renewed commitment to occupational safety and health led to the endorsement of the Workers' Health Global Plan for Action in 2007 (http://apps.who.int/gb/ebwha/pdf_files/WHA60/A60_R26-en.pdf). Out of this renewed effort for improving occupational safety and health, WHO (2010) developed and proposed a healthy workplace model that encompasses four elements:

1. Physical environment or the "structure, air, machinery, furniture, products, chemicals, materials and production processes in the workplace" (p. 9).

2. Psychosocial environment or the "organizational culture as well as attitudes, values, beliefs and daily practices in the enterprise that affect the mental and physical well-being of employees" (p. 10), also known as workplace stressors.

3. Personal health resources in the workplace or the "health services, information, resources, opportunities, flexibility and otherwise supportive environment an enterprise provides to workers to support or motivate their efforts to improve or maintain healthy personal lifestyles, as well as to monitor and support their physical and mental health" (p. 11).

4. Enterprise community involvement or the "activities in which an enterprise might engage, or expertise and resources it might provide, to support the social and physical wellbeing of a community in which it operates" (p. 13).

This model includes both the internal work environment (physical and psychosocial work environment and personal health resources in the workplace) and the linkage between the organization and its environment and the community. This broad approach goes beyond the workplace itself, which has been the target of many human factors efforts. It challenges the human factors professionals and researchers to think about larger social, economic, and environmental problems (Moray, 2000; Smith et al., 1994, 2009).

Pfeffer (2010) proposes to broaden the concept of sustainability by including not only natural and physical resources but also human and social resources. His paper, entitled "Building sustainable organizations: The human factor," clearly calls for organizations to go beyond environmental sustainability and to embrace the concept of "human sustainability." Organizations should, therefore, develop actions and programs aimed at social responsibility as well as invest in management practices that improve employee physical and

psychological well-being. Human sustainability can lead to business benefits, such as brand building and product differentiation (Pfeffer, 2010). Companies that invest in human sustainability may build a positive reputation that can attract additional customers.

## 4.2 Impact of Organizational Decisions on Human Sustainability

Pfeffer (2010) describes three types of decisions made by organizations that can affect human sustainability: (1) employer-funded health insurance, (2) layoffs and downsizing, and (3) work schedules. Employers who provide access to health insurance help their employees to improve their economic well-being as well as health and wellness. However, the empirical evidence for this relationship between employer-funded health insurance and human sustainability is rather weak. O'Brien (2003) identified various effects of offering health insurance on employee performance and human sustainability. First, the productivity of organizations depends on the quality of their employees and by offering health insurance employers can attract high-quality workers. Second, by offering access to health insurance, organizations may be able to retain workers. Third, offering health insurance can increase productivity because healthy workers are more productive than unhealthy workers. Finally, offering health insurance can increase employee satisfaction, and employees who do not have to worry about their own health or the health of their family members may be more productive (O'Brien, 2003). There is, however, limited evidence for these four effects of access to health insurance on employee performance. Buchmueller (2000) reviewed the economical literature to examine whether there are any spill-over effects of providing health insurance to employees. Based on his review he concluded that there is little evidence for the effect of health insurance on worker health and productivity, reduced turnover, or reduced employer costs associated with workers' compensation and absenteeism (Buchmueller, 2000). Some studies have shown that employees in jobs with health insurance coverage change jobs less frequently than workers without health insurance (Madrian, 1994; Monheit and Cooper, 1994), while other studies have shown that offering health insurance has no effect on turnover (Holtz-Eakin, 1994; Kapur, 1998). There is little evidence that having access to health insurance is related to lower turnover. According to O'Brien (2003), the existing literature has not taken into account the effect of ill-health on productivity. There is ample evidence that people with poor health or health conditions work less (Bartel and Taubman, 1979; Rizzo et al., 1998). Therefore, there is room for additional high-quality research to further investigate the relationship between employer-funded health insurance and human sustainability, in particular in the areas of employee satisfaction and well-being.

Decisions made by organizations such as layoffs and downsizing can have a major negative impact on workers affected by those changes as well as a profound impact on the community where the organization is located. A layoff can be considered a major life event and stressor that impacts the individual being laid off,

his/her family, his/her community, and society at large. Workers lose much more than a job when they are laid off. Jobs are an economic necessity and provide many psychological and social benefits. Losing one's job lessens worker feelings of self-worth and dignity. Losing one's job ranks alongside a death in the family with regard to stress because it leaves an emptiness that is difficult to fill (Hansen, 2009). Results of a case study assessing the impact of layoffs in a small community in Texas showed that 58% of study participants reported having increased health problems after the layoff (Virick, 2003). Unemployment has been linked to the following stress-related negative health outcomes: higher mortality rates, increased risk of heart attack, low-birthweight offspring, infectious diseases, chronic respiratory diseases, gastrointestinal disorders, depression, alcoholism, and suicide (Broadhead et al., 1983; Cassell, 1976; Dew et al., 1992; Hamilton et al., 1990; House, 1981; Kivimäki et al., 2003). In an interesting study, Dew et al. (1987) compared the long-term effects of two community-wide stressors: the Three Mile Island nuclear accident and widespread unemployment due to layoff in demographically comparable samples of women. Results of the study showed a remarkable similarity in the stressors' effect: Levels of various mental and physical health symptoms were elevated to similar degrees in both samples one year following the stressor, and symptoms remained elevated in both samples up to three years later. Based on studies on the effects of unemployment in several industrial countries, Brenner (1983, 1987a, 1987b, 1987c) calculated that for every 1% increase in the unemployment rate in the United States (an additional 1.5 million people out of work), an additional 47,000 deaths can be expected, including 26,000 from heart attacks, about 1200 from suicide, 831 murders, and 635 related to alcohol consumption. Results of a study by Benson and Fox (2004) showed that unstable employment increases the risk of intimate partner violence. For couples where the male was always employed, the rate of intimate partner violence was 4.7%. When men experienced one period of unemployment, the rate rose to 7.5%, and when men experienced two or more periods of unemployment, the rate of intimate partner violence rose to 12.3%.

Work hours can lead to work–family conflict if there is insufficient or inadequate time for workers to spend with family and friends (e.g., long work hours, night and week-end work) (Demerouti et al., 2004; Frone and Russell, 1992; Frone, 1997; Grant-Vallone and Donaldson, 2001; Kinnunen et al., 2004).

## 4.3 Sustainable Organizations from the ODAM Viewpoint

Historically, the human factors discipline has focused on the individual employee at the workplace level. Although some human factors research and practice have taken social and economic issues into account, they have typically not paid much attention to the environment (Steimle and Zink, 2006). Recently, macroergonomic approaches have embraced the broader system in which people work, including the environment (Hendrick and Kleiner, 2002). Macroergonomics is

concerned with the optimization of organizational and work system design through consideration of relevant personnel and technological and environmental variables and their interactions (Hendrick and Kleiner, 2001).

Zink and colleagues (2008) have proposed an ODAM approach to designing sustainable organizations that includes three elements: (1) focus on human needs (i.e., human factors and ergonomics), (2) inter- and intragenerational equity (i.e., every generation benefits from the heritage of previous generations and is concerned with the needs of future generations), and (3) three pillars of sustainable development with social, economic, and environmental objectives. Corporate social responsibility is therefore a key element of corporate sustainability: A company is more likely to grow and thrive over time (i.e., be sustained) if the company invests in its workers by providing good working conditions (internal focus) and contributes to its community (external focus).

Corporate sustainability can be defined as "meeting the needs of a firm's direct and indirect stakeholders (such as shareholders, employees, clients, pressure groups, communities, etc.) without compromising its ability to meet the needs of future stakeholders as well" (Dyllick and Hockerts, 2002, p. 131). Three concepts are important in achieving corporate sustainability: (1) a sustainable corporation considers not only economic but also social and environmental prerequisites and impacts of its actions as well as the interdependencies between them, (2) corporate sustainability requires a long-term business orientation as a basis for satisfying stakeholders' needs now and in the future, and (3) a sustainable corporation should generate income from its financial, natural, and social capital without depleting the capital (Dyllick and Hockerts, 2002).

Among a company's stakeholders are its employees, and, consequently, all efforts to achieve corporate sustainability should involve employees. Companies' policies and actions should be aimed at preserving its human capital. For example, many countries have a rapidly aging population, especially in Europe and to a lesser extent in the United states. In these countries, companies should develop policies and implement programs aimed at protecting their human capital, in particular older workers.

A sustainable organization has the flexibility and adaptability to respond readily to both internal and external influences. This might include shifts in the business climate, market opportunities, or the labor market as well as new ideas or challenges that may develop internally. Without full employee engagement, the organization will lack the flexibility and adaptability to respond in a timely manner to changing circumstances. A sustainable organization has employee stability and engagement as well as effective formal and informal communication channels and work processes that enable it to adjust to changing circumstances in an ongoing manner.

## 5 PRINCIPLES FOR WORK SYSTEM DESIGN AND ANALYSIS

In previous sections we described some of the theories and research that have been developed and tested over the past century about how organizations manage their workforce to provide benefits to the organization and the employees. In general, we have moved from command and control to a focus on educating employees and to recognizing the value of engaging employees' hearts and minds in addressing the challenges of the organization (Carayon and Smith, 2000; Hackman, 2002; Lawler, 1986, 1996, 2003; McGregor, 1960; Smith and Carayon-Sainfort, 1989; Smith and Carayon, 1995). To take it a step further, we believe the United States is now in the midst of a major societal shift that has implications for how effective organizations will be in attracting and retaining the most talented and creative people in the workforce. These individuals have high expectations for themselves; enough talent to find alternatives to the traditional career in a large organization; and a desire to find meaning, balance, authenticity, and spiritual fulfillment in their lives. Organizations that are viewed as hampering these human desires will find it difficult to attract and keep the best employees to the long-term detriment of the organization.

### 5.1 Model of Work System

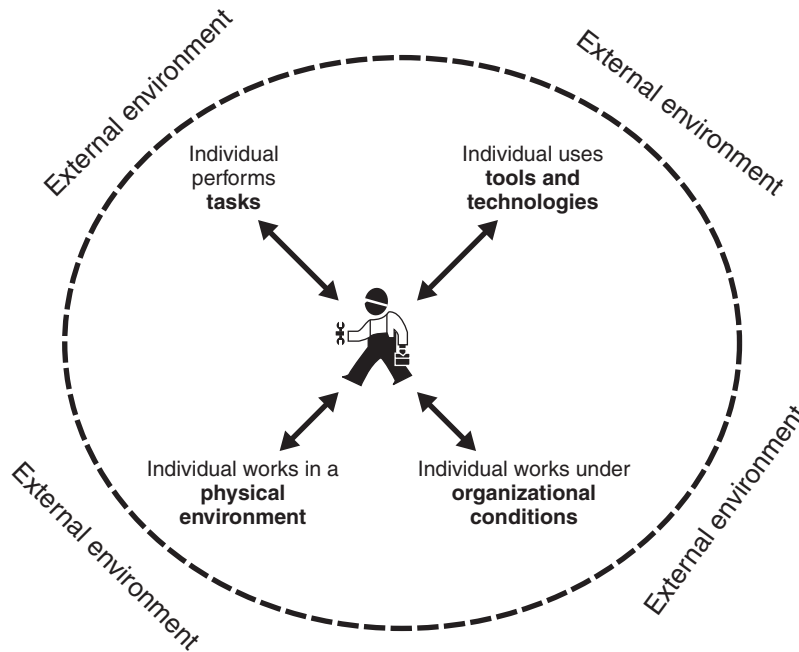
In order to address these challenges, we propose an approach built on systems theory and work complexity. In 1989, Smith and Carayon-Sainfort (1989) proposed the work system model that defines various elements of work and the interactions between the work elements (see Figure 1). Because the work system model is anchored in the discipline of human factors and ergonomics, the person is at the center of the work system: The person has *physical*, *cognitive*, and *psychosocial characteristics and needs* that can influence his/her interactions with the rest of the work system. The person performs *tasks* using various *tools and technologies* in a specific *physical environment*. There are a number of *organizational conditions* that can influence the person and the rest of the work system. From an ODAM viewpoint, it is important to consider the cognitive, physical, and psychosocial needs and characteristics of the individual who is at the center of the work system. This is in line with the International Ergonomics Association (IEA) definition of human factors (or ergonomics) (IEA, 2000): The discipline of human factors (or ergonomics) includes three broad domains of specialization: (1) physical ergonomics, (2) cognitive ergonomics, and (3) organizational ergonomics. The work system model encompasses all three domains of human factors specialization. For instance, relevant topics for physical ergonomics include working postures: Working postures are defined by the interactions between the individual, the tasks, the physical environment, and the design of tools and technologies. In addition, there has been increasing recognition of the importance of psychosocial work factors as determinants of physical stress: A worker who is under psychosocial stress (e.g., time pressure) may increase his or her work pace, thus increasing the likelihood that awkward postures may lead to physical stress and health problems. Topics relevant to cognitive ergonomics include mental workload, which has been conceptualized as resulting from the lack of fit between task demands and individual


**Figure 1**  Elements of the work system and its external environment. (Adapted from Smith and Carayon-Sainfort, 1989).

resources and capabilities. However, it has become clear that mental workload is also influenced by larger organizational issues that can affect specific task demands (MacDonald, 2003). For instance, an organization may restrict the number of rest breaks taken by workers and increase the time pressure put on workers; this will definitely increase the task demands and will likely lead to increased mental workload. Therefore, from a human factors perspective, it is important to consider all elements of the work system and their interactions. The work system should be designed to accommodate the physical, cognitive, and psychosocial characteristics of the individual and meet their physical, cognitive, and psychosocial needs.

The work system model allows the consideration of all three groups of relevant human factors topics, that is, physical, cognitive, and organizational ergonomic issues. The work system model, however, is limited as it describes the work elements of an individual. This conceptualization of the work system for looking at single individuals has been recently expanded to consider how to design an organization. Carayon and Smith (2000) describe how an organization can be conceptualized as a collection of multiple work systems: The organization is comprised of individual employees with their own work systems. The work systems of the individual employees interact with each other; therefore, it is important to consider the interactions and interfaces between the different work systems. One way of designing the interactions between the work systems is to consider *organizational processes.* Any organization has multiple processes, including production processes, design processes, and support processes (e.g., human resources, supply chain

management). A process consists of a series of tasks that are temporally interdependent and that transform a range of inputs into an output. The connections between work systems have been examined for patient care processes, such as the outpatient surgery process (Carayon, 2009; Schultz et al., 2007). The work system elements (individual, task, tools/technologies, physical environment, and organizational conditions) can be used to describe the physical, cognitive, and organizational ergonomic issues related to care processes (Carayon et al., 2004; Schultz et al., 2007). Therefore, a care process can be considered as a series of tasks performed by various individuals; each task of the process is performed by one or several individuals who use multiple tools and technologies. The process tasks are performed in a physical environment. The organizational conditions of importance to process design include communication and coordination across tasks. In particular, in care processes, transitions of care across health care providers or settings can produce a range of communication and coordination issues related to information flow and care accountability (Carayon et al., 2004).

Our previous discussion of sustainable organizations emphasizes the need to consider the larger environment (including the social environment) in which organizations evolve. Therefore, a useful expansion of the work system model is to consider the larger environment in which the work system functions (Kleiner, 2008). According to the sociotechnical systems theory (Cherns, 1987; Clegg, 2000; Pasmore, 1988), there are two-way interactions between the system and its environment: (1) the environment influences the work system and (2) the work system influences the environment.

Figure 1 represents an expansion of the work system model that includes the environment; the dashed line between the work system and the environment implies that there are two-way interactions between the system and its environment. The external environment is comprised of the physical environment, the social environment, and the legal/regulatory/political/professional environment. Other human factors approaches have also considered the role of the larger environment in influencing work and workers. For instance, Rasmussen (2000) proposed a hierarchy of system levels that interact and influence each other. Moray (2000) has proposed a similar hierarchical approach to ergonomic system design.

A range of macroergonomic methods are available to analyze a work system, including both qualitative (e.g., interview and focus group) and quantitative (e.g., survey) methods. For additional information, see the section on macroergonomic methods in the *Handbook of Human Factors and Ergonomics Methods* by Stanton and colleagues (2004).

## 5.2 Continuous Improvement of Work System Design

Practitioners and researchers in organizational design and management have long recognized the importance of the continuous improvement process: The design of work systems should be a continuous process. For instance, when revisiting the principles of sociotechnical system (STS) design, Clegg (2000) emphasizes that the STS design process extends over time. New business and employee needs may arise, requiring the work system design to be reassessed and adapted. The dynamic nature of the work system and its environment clearly calls for a design approach based on continuous improvement. Carayon (2006) has discussed the need for continuous cycles of work system design, implementation, and continuous improvement/adaptation. Her principles for continuous work system improvement are summarized in Table 2.

**Table 2 Principles for Macroergonomic Continuous System Adaptation and Improvement**

| Principle | Description |
| --- | --- |
| Participation | Active participation of all stakeholders in system design activities (e.g., participatory ergonomics) |
| Interactions | Continuous interactions between multiple work systems and between work systems and their environment |
| Design | Continuous work system design and redesign |
| Adaptation | Adaptation of work system for long-term health, productivity, and sustainability |
| Learning | Support for both individual and organizational learning (e.g., collaborative problem definition, analysis, and modeling) |
| Sense making | Sense making of on-going changes and their impact |

*Source*: From Carayon, 2006.

The field of quality improvement and Total quality management has had a profound influence on organizational activities; many businesses routinely employ the PDCA, or plan−do−check−act, cycle (Deming, 1986). This continuous cycle of planning, implementation, assessment, and improvement can be recognized in the WHO (2010) model of healthy workplace continual improvement process. The WHO model involves the following eight steps:

1. Mobilization of employers, managers, and workers for work system change. This step requires a deep understanding of the needs, values, and priority issues of various members of the organization in order to identify the important issue(s) that will mobilize them.

2. Creation of a multidisciplinary team to work on implementing a work system change. The team should be provided with adequate resources to achieve its objectives. Professionals in the areas of occupational health and safety, human resources and engineering should be involved in this team as well as representatives from the employer and the employees.

3. Assessment of work system and employee and organizational health and performance. This will typically involve the use of various tools and methods to assess, for instance, worker health, workplace hazards, and turnover and productivity.

4. Priority setting for work system change. Several criteria are likely to be used to identify the work system change to be implemented, including limiting exposure to physical or psychosocial hazards, ease of implementing change, and likelihood of success.

5. Planning for implementation of work system change. The plan may be very simple or complex depending on the work system change and the size and complexity of the organization. Each action of the plan should have clear objectives and be assigned to specific members of the organization.

6. Implementation of work system change.

7. Evaluation of work system change. It is important to evaluate the pluses and minuses of the work system change, in particular with regard to the initial objectives. The evaluation should also include an evaluation of the planning phase and the implementation process.

8. Continuous improvement. This last step is actually the first step of the next cycle of work system changes. Additional changes may be necessary based on the evaluation results.

## 6 CONCLUSION

In this chapter, we have conducted an extensive historical review of various theories and approaches to organizational design and management. In the past two

decades, the human factors and ergonomics discipline has recognized the importance of organizational design and management; this concept is known as macroergonomics (Hendrick, 1991). Human factors researchers and professionals recognize the need to consider organizational and sociotechnical issues when designing work systems. For instance, when attempting to eliminate physical stressors such as awkward postures, ergonomists understand the need to consider organizational policies such as work schedules and rest−break schedules that can influence or mitigate the impact of awkward postures on workers. Other interactions between micro- and macroergonomic issues are discussed in this chapter and have been reviewed by others (Zink, 2000).

Our review of the literature also shows the need for human factors researchers and professionals to be aware of theoretical developments in connected fields and disciplines, in particular psychology, sociology, business, and occupational and public health. This need for multidisciplinary approaches to work system design aimed at enhancing performance, safety, quality of working life, and well-being has been discussed by other human factors researchers (Carayon, 2006; Moray, 2000; Rasmussen, 2000). As the world has become flat (Friedman, 2005), problems have become increasingly complex and multidimensional, requiring expertise in multiple areas and disciplines. Therefore, human factors researchers and professionals should be encouraged to team up with relevant domain experts in analyzing and improving system design.

The discipline of human factors and ergonomics has grown significantly in the past 50 years; this has led to specialization of human factors professionals and ergonomists in specific domains of human factors and ergonomics (Wilson, 2000). This specialization may have come at the expense of a true system design approach that recognizes interactions between system levels and the various levels of system design (Carayon, 2009; Karsh and Brown, 2010; Rasmussen, 2000). This chapter on human factors in organizational design and management proposes some directions for the human factors and ergononomics discipline to examine the larger organizational system as well as the environment in which organizations function and evolve. This should heighten the awareness of the organization and its environment among human factors professionals and researchers. We recommend that human factors professionals and researchers develop concepts, theories, and methods for building healthy and sustainable organizations.

# CHAPTER 19

# SITUATION AWARENESS

**Mica R. Endsley**
**SA Technologies, Inc.**
**Marietta, Georgia**

## 1 INTRODUCTION

As we move into the twenty-first century, the biggest challenge within most industries and the most likely cause of an accident receives the label of human error. This is a most misleading term, however, that has done much to sweep the real problems under the rug. It implies that people are merely careless or poorly trained or somehow not very reliable in general. In fact, in the vast majority of these accidents the human operator was striving against significant challenges. On a day-to-day basis, they cope with hugely demanding complex systems. They face both data overload and the challenge of working with a complex system. They are drilled with long lists of procedures and checklists designed to cope with some of these difficulties, but from time to time they are apt to fail. Industry's typical response to such failures has been more procedures and more systems, but unfortunately, this only adds to the complexity of the system. In reality, the person is not the cause of these errors but is the final dumping ground for the inherent problems and difficulties in the technologies we have created. The operator is usually the one who must bring it all together and overcome whatever failures and inefficiencies exist in the system.

So why are people having trouble coping with the present technology and data explosion? The answer lies in understanding how people process the vast amount of data around them to arrive at effective performance.

If these accidents are examined in detail, one finds that the operators generally have no difficulty in performing their tasks physically and no difficulty in knowing what is the correct thing to do, but they continue to be stressed by the task of *understanding what is going on in the situation*. Developing and maintaining a high level of *situation awareness* are the most difficult parts of many jobs and some of the most critical and challenging tasks in many domains today.

*Situation awareness* (SA) can be thought of as an internalized mental model of the current state of the operator's environment. All of the incoming data from the many systems, the outside environment, fellow team members, and others [e.g., other aircraft and air traffic control (ATC)] must all be brought together into an integrated whole. This integrated picture forms the central organizing feature from which all decision making and action take place (Figure 1).

A vast portion of the operator's job is involved in developing SA and keeping it up to date in a rapidly changing environment. This is a task that is not simple in light of the complexity and sheer number of factors that must be taken into account to make effective decisions. The key to coping in the information age is developing systems that support this process, yet this is where current technologies have left human operators the most vulnerable to error. Problems with SA were found to be the leading causal factor in a review of military aviation
**Figure 1**   Sources of SA. (From Endsley, 1995d, 1997.)

mishaps (Hartel et al., 1991) and in a study of accidents among major air carriers; 88% of those involving human error could be attributed to problems with SA (Endsley, 1995c).

A similar review of errors in other domains, such as air traffic control (Rodgers et al., 2000) or nuclear power (Hogg et al., 1993; Mumaw et al., 1993), showed that this is not a problem limited to aviation but one faced by many complex systems.

Successful system designs must deal with the challenge of combining and presenting vast amounts of data now available from many technological systems in order to provide true SA (whether it is to a pilot, a physician, a business manager, or an automobile driver). An important key to the development of complex technologies is understanding that true SA exists only in the mind of the human operator. Therefore, presenting a ton of data will do no good unless the data are transmitted, absorbed, and assimilated successfully and in a timely manner by the human in order to form SA. Unfortunately, most systems fail in this regard, leaving significant SA problems in their wake (Figure 2).

## 1.1   Definition of Situation Awareness

Although much SA research (and the term) originated within the aviation domain, SA as a construct is widely studied and exists as a basis of performance across many different domains, including air traffic control,

military operations, education, driving, train dispatching, maintenance, and weather forecasting. One of the earliest and most widely applicable SA definitions describes it as "the perception of the elements in the environment within a volume of time and space, the comprehension of their meaning and the projection of their status in the near future" (Endsley, 1988). SA therefore involves perceiving critical factors in the environment (level 1 SA), understanding what those factors mean, particularly when integrated together in relation to the operator's goals (level 2), and at the highest level an understanding of what will happen with the system in the near future (level 3). These higher levels of SA allow people to function in a timely and effective manner, even with very complex and challenging tasks. Each of these levels will be discussed in more detail.

### 1.1.1   Level 1: Perception of the Elements in the Environment

The first step in achieving SA is to perceive the status, attributes, and dynamics of relevant elements in the environment. A pilot needs to perceive important elements such as other aircraft, terrain, system status, and warning lights along with their relevant characteristics. In the cockpit, just keeping up with all of the relevant system and flight data, other aircraft, and navigational data can be quite taxing. An army officer needs to detect enemy, civilian, and friendly positions and actions, terrain features, obstacles, and weather. An air traffic controller or automobile driver has a different set of information that is needed for SA.

### 1.1.2   Level 2: Comprehension of the Current Situation

Comprehension of the situation is based on a synthesis of disjoint level 1 elements. Level 2 SA goes beyond simply being aware of the elements that are present to include an understanding of the significance of those elements in light of one's goals. The operators put together level 1 data to form a holistic picture of the environment, including a comprehension of the significance of objects and events. For example, upon seeing warning lights indicating a problem during takeoff, the pilot

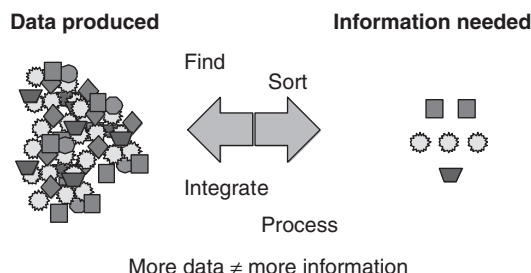

**Figure 2**   Information gap. (From Endsley, 2000b.)

must quickly determine the seriousness of the problem in terms of the immediate air worthiness of the aircraft and combine this with knowledge on the amount of runway remaining in order to know whether or not it is an abort situation. A novice operator may be capable of achieving the same level 1 SA as more experienced ones but may fall far short of being able to integrate various data elements along with pertinent goals in order to comprehend the situation.

### 1.1.3 Level 3: Projection of the Future Status

It is the ability to project the future actions of the elements in the environment, at least in the very near term, that forms the third and highest level of SA. This is achieved through knowledge of the status and dynamics of the elements and a comprehension of the situation (both levels 1 and 2 SA). Amalberti and Deblon (1992) found that a significant portion of experienced pilots' time was spent in anticipating possible future occurrences. This gives them the knowledge (and time) necessary to decide on the most favorable course of action to meet their objectives. This ability to project can similarly be critical in many other domains, including driving, plant control, and sports.

### 1.2 Elements of Situation Awareness

The "elements" of SA in the definition are very domain specific. Examples for air traffic control are shown in Table 1. These elements are clearly observable, meaningful pieces of information for an air traffic controller. Things such as aircraft type, altitude, heading, and flight plan, and restrictions in effect at an airport or conformance to a clearance each comprise meaningful elements of the situation for an air traffic controller. The elements that are relevant for SA in other domains can be delineated similarly. Cognitive task analyses have been conducted to determine SA requirements in commercial aviation (Farley et al., 2000), fighter aircraft (Endsley, 1993), bomber aircraft (Endsley, 1989b), and infantry operations (Matthews et al., 2004), among others.

## 2 DEVELOPING SITUATION AWARENESS

Several researchers have developed theoretical formulations for depicting the role of numerous cognitive processes and constructs on SA (Endsley, 1988, 1995d; Fracker, 1988; Taylor, 1990; Tenney et al., 1992; Taylor and Selcon, 1994; Adams et al., 1995; Smith and Hancock, 1995). There are many commonalties in these efforts, pointing to essential mechanisms that are important for SA. The key points are discussed here; however, more details on each model may be found in these readings. Reviews of these theoretical models of SA are also provided in Pew (1995), Durso and Gronlund (1999), and Endsley (2000b).

Endsley (1988, 1990b, 1995d) describes a theoretical framework model of SA which is summarized in Figure 3. In combination, the mechanisms of short-term sensory memory, perception, working memory, and long-term memory form the basic structures on which

**Table 1 Elements of SA for Air Traffic Control**

#### Level 1 SA

Aircraft
  Aircraft identification (ID), combat identification (CID), beacon code
  Current route (position, heading, aircraft turn rate, altitude, climb/descent rate, ground speed)
  Current flight plan (destination, filed plan)
  Aircraft capabilities (turn rate, climb/descent rate, cruising speed, max/min speed)
  Equipment on board
  Aircraft type
  Fuel/loading
  Aircraft status
    Activity (en route, arriving, departing, handed off, pointed out)
    Level of control, instrument flight rules (IFR), visual flight rules (VFR), flight following, VFR on top, uncontrolled object)
    Aircraft contact established
    Aircraft descent established
  Communications (present/frequency)
  Responsible controller
  Aircraft priority
    Special conditions
    Equipment malfunctions
    Emergencies
  Pilot capability/state/intentions
  Altimeter setting
Emergencies
  Type of emergency
  Time on fuel remaining
  Souls on board
Requests
  Pilot/controller requests
  Reason for request
Clearances
  Assignment given
  Received by correct aircraft
  Readback correct/complete
  Pilot acceptance of clearance
  Flight progress strip current
Sector
  Special airspace status
  Equipment functioning
  Restrictions in effect
  Changes to standard procedures
Special operations
  Type of special operation
  Time begin/terminate operations
  Projected duration
  Area and altitude effected
ATC equipment malfunctions
  Equipment affected

*(continued overleaf)*

**Table 1  Continued**

Alternate equipment available
Equipment position/range
Aircraft in outage area
Airports
Operational status
Restrictions in effect
Direction of departures
Current aircraft arrival rate
Arrival requirements
Active runways/approach
Sector saturation
Aircraft in holding (time, number, direction,
leg length)
Weather
Area affected
Altitudes affected
Conditions (snow, icing, fog, hail, rain, turbulence,
overhangs)
Temperatures
Intensity
Visibility
Turbulence
Winds
IFR/VFR conditions
Airport conditions

**Level 2 SA**

Conformance
Amount of deviation (altitude, airspeed, route)
Time until aircraft reaches assigned altitude, speed,
route/heading
Current separation
Amount of separation between
aircraft/objects/airspace/ground along route
Deviation between separation and prescribed
Limits
Number/timing aircraft on routes
Altitudes available
Timing
Projected time in airspace
Projected time until clear of airspace
Time until aircraft landing expected
Time/distance aircraft to airport
Time/distance until visual contact
Order/sequencing of aircraft
Deviations
Deviation aircraft/landing request
Deviation aircraft/flight plan
Deviation aircraft/pilot requests
Other sector/airspace
Radio frequency
Aircraft duration/reason for use

**Table 1  Continued**

Significance
Impact of requests/clearances on:
Aircraft separation/safety
Own/other sector workload
Impact of weather on:
Aircraft safety/flight comfort
Own/other sector workload
Aircraft flow/routing (airport arrival rates, flow rates,
holding requirements aircraft routes, separation
procedures)
Altitudes available
Traffic advisories
Impact of special operations on sector
Operations/procedures
Location of nearest capable airport for aircraft
type/emergency
Impact of malfunction on: routing, communications,
flow control, aircraft, coordination procedures,
other sectors, own workload
Impact on workload of number of aircraft sector
demand vs. own capabilities
Confidence level/accuracy of information
Aircraft ID, position, altitude, airspeed, heading
Weather
Altimeter setting

**Level 3 SA**

Projected aircraft route (current)
Position, fight plan, destination, heading, route,
altitude, climb/descent rate, airspeed, winds,
groundspeed, intentions, assignments
Projected aircraft route (potential)
Projected position $x$ at time $t$
Potential assignments
Projected separation
Amount of separation along route
(aircraft/objects/airspace/ground)
Deviation between separation and prescribed limits
Relative projected aircraft routes
Relative timing along route
Predicted changes in weather
Direction/speed of movement
Increasing/decreasing in intensity
Impact of potential route changes
Type of change required
Time and distance until turn aircraft amount of
turn/new heading, altitude, route change required
Aircraft ability to make change
Projected number of changes necessary
Increase/decrease length of route
Cost/benefit of new clearance
Impact of proposed change on aircraft separation

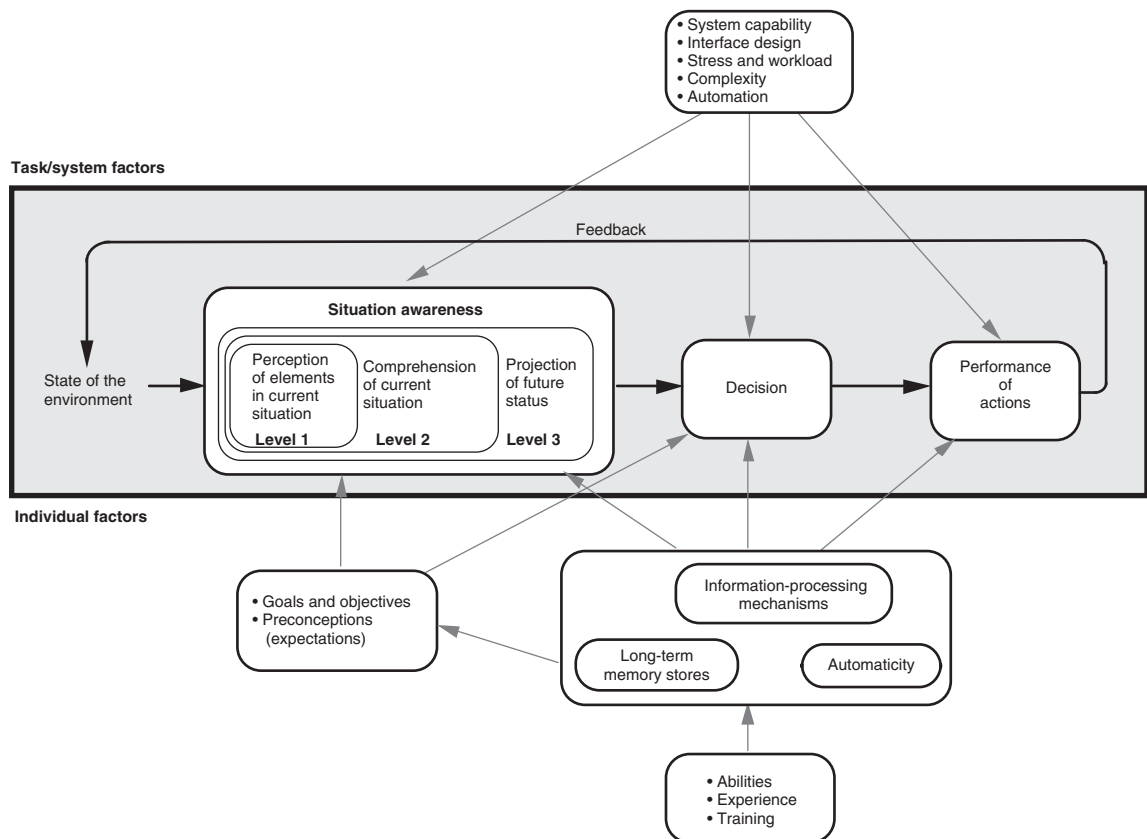

**Figure 3** Model of SA in dynamic decision making. (From Endsley, 1995d, 1997.)

SA is based. According to this model, which is formulated in terms of information-processing theory, elements in the environment may initially be processed in parallel through preattentive sensory stores, where certain properties are detected, such as spatial proximity, color, simple properties of shapes, and movement, providing cues for further focalized attention. Those objects that are most salient are processed further using focalized attention to achieve perception. Limited attention creates a major constraint on an operator's ability to perceive multiple items accurately in parallel and, as such, is a major limiting factor on a person's ability to maintain SA in complex environments.

The description thus far accurately depicts only simple data-driven processing; however, the model also shows a number of other factors that affect this process. First, attention and the perception process can be directed by the contents of both working and long-term memory. For instance, advance knowledge regarding the location of information, the form of the information, the spatial frequency, the color, or the overall familiarity and appropriateness of the information can all significantly facilitate perception. Long-term memory also serves to shape the perception of objects in terms of known

categories or mental representations. Categorization tends to occur almost instantly.

For operators who have not developed other cognitive mechanisms (novices and those in novel situations), the perception of the elements in the environment (the first level of SA) is significantly limited by attention and working memory. In the absence of other mechanisms, most of the operator's active processing of information must occur in working memory. New information must be combined with existing knowledge and a composite picture of the situation developed. Projections of future status and subsequent decisions as to appropriate courses of action will also occur in working memory. Working memory will be significantly taxed while simultaneously achieving the higher levels of SA, formulating and selecting responses, and carrying out subsequent actions.

In actual practice, however, goal-directed processing and long-term memory (often in the form of mental models and schema) can be used to circumvent the limitations of working memory and direct attention more effectively. First, much relevant knowledge about a system is hypothesized to be stored in mental models. Rouse and Morris (1985, p.7) define mental models as "mechanisms whereby humans are able to generate descriptions of system purpose and form, explanations

of system functioning and observed system states, and predictions of future states."

Mental models are cognitive mechanisms that embody information about system form and function; often, they are relevant to a physical system (e.g., a car, computer, or power plant) or an organizational system (e.g., how a university, company, or military unit works). They typically contain information about not only the components of a particular system but also how those components interact to produce various system states and events. Mental models can significantly aid SA as people recognize key features in the environment that map to key features in the model. The model then creates a mechanism for determining associations between observed states of components (comprehension) and predictions of the behavior and status of these elements over time. Thus, mental models can provide much of the higher levels of SA (comprehension and projection) without loading working memory.

Also associated with mental models are schema: prototypical classes of states of the system (e.g., an engine failure, an enemy attack formation, or a dangerous weather formation). These schema are even more useful to the formation of SA since these recognized classes of situations provide an immediate one-step retrieval of the higher levels of SA, based on pattern matching between situation cues and known schema in memory. Very often scripts, set sequences of actions, have also been developed for schema, so that much of the load on working memory for generating alternative behaviors and selecting among them is also diminished. These mechanisms allow the operator simply to execute a predetermined action for a given recognized class of situations (based on their SA). The current situation does not need to be exactly like the one encountered previously, due to the use of categorization mapping; as long as a close-enough mapping can be made into relevant categories, a situation can be recognized and comprehended in terms of the model, predictions made, and appropriate actions selected. Since people have very good pattern-matching abilities, this process can be almost instantaneous and produce a much lower load on working memory, which makes high levels of SA possible, even in very demanding situations.

Expertise therefore plays a major role in the SA process. For novices or those dealing with novel situations, decision making in complex and dynamic systems can be very demanding or impossible to accomplish successfully in that it requires detailed mental calculations based on rules or heuristics, placing a heavy burden on working memory. Where experience has allowed the development of mental models and schema, pattern matching between the perceived elements in the environment and existing schema/mental models can occur on the basis of pertinent cues that have been learned. Thus, the comprehension and future projection required for the higher levels of SA can be developed with far less effort and within the constraints of working memory. When scripts have been developed, tied to these schema, the entire decision-making process will be greatly simplified.

The operator's goals also play an important part in the process. These goals can be thought of as ideal states of the system model that the operator wishes to achieve. In what Casson (1983) has termed a *top-down* decision-making process, the operator's goals and plans will direct which environmental aspects are attended to in the development of SA. Goal-driven or top-down processing is very important in the effective information process and development of SA. Conversely, in a *bottom-up* or data-driven process, patterns in the environment may be recognized which will indicate to the operator that different plans will be necessary to meet goals or that different goals should be activated.

Alternating between "goal driven" and "data driven" is characteristic of much human information processing and underpins much of the SA development in complex worlds. People who are purely data driven are very inefficient at processing complex information sets; there is too much information, so they are simply reactive to the cues that are most salient. People who have clearly developed goals, however, will search for information that is relevant to those goals (on the basis of the associated mental model, which contains information on which aspects of the system are relevant to goal attainment), allowing the information search to be more efficient and providing a mechanism for determining the relevance of the information that is perceived. If people are only goal driven, however, they are likely to miss key information that would indicate that a change in goals is needed (e.g., no longer the goal "land the airplane" but the goal "execute a go-around"). Thus, effective information processing is characterized by alternating between these modes: using goal-driven processing to find and process efficiently the information needed for achieving goals and data-driven processing to regulate the selection of which goals should be most important at any given time.

The development of SA is a dynamic and ongoing process that is effected by these key cognitive mechanisms. Although it can be very challenging in many environments, with mechanisms that can be developed through experience (schema and mental models), we find that people are able to circumvent certain limitations (working memory and attention) to develop sufficient levels of SA to function very effectively. Nevertheless, developing accurate SA remains a very challenging feature in many complex settings and demands a significant portion of an operator's time and resources. Thus, developing selection batteries, training programs, and system designs to enhance SA is a major goal in many domains.

## 3  SITUATION AWARENESS CHALLENGES

Building and maintaining SA can be a difficult process for people in many different jobs and environments. Pilots report that the majority of their time is generally spent trying to ensure that their mental picture of what is happening is current and correct. The same can be said for people in many other domains, where systems are complex and there is a great deal of information to understand, where information changes rapidly, and where information is difficult to obtain. The reasons for this have been captured in terms of eight SA demons, factors that work to undermine SA in many systems and environments (Endsley et al., 2003).

### 3.1 Attentional Tunneling

Successful SA is highly dependent on constantly juggling one's attention between different aspects of the environment. Unfortunately, there are significant limits on people's ability to divide their attention across multiple aspects of the environment, particularly within a single modality, such as vision or sound, and thus attention sharing can occur only to a limited extent (Wickens, 1992). They can often get trapped in a phenomenon called *attentional narrowing* or *tunneling* (Bartlett, 1943; Broadbent, 1954; Baddeley, 1972).

When succumbing to attentional tunneling, they lock in on certain aspects or features of the environment they are trying to process and will intentionally or inadvertently drop their scanning behavior. In this case, their SA may be very good on the part of the environment of their concentration but will quickly become outdated on other aspects they are not watching. Attentional narrowing has been found to undermine SA in tasks such as flying and driving and poses one of the most significant challenges to SA in many domains.

### 3.2 Requisite Memory Trap

The limitations of working memory also create a significant SA demon. Many features of the situation may need to be held in memory. As a person scans different information from the environment, information accessed previously must be remembered and combined with new information. Auditory information must also be remembered, as it cannot be revisited in the way that visual displays can. Given the complexity and sheer volume of information required for SA in many systems, these memory limits create a significant problem for SA. System designs that necessitate that people remember information, even short term, increase the likelihood of SA error.

### 3.3 Workload, Anxiety, Fatigue, and Other Stressors

Stressors such as anxiety, time pressure, mental workload, uncertainty, noise or vibration, excessive heat or cold, poor lighting, physical fatigue, and working against one's circadian rhythms are unfortunately an unavoidable part of many work environments. These stressors can act to reduce SA significantly by further reducing an already limited working memory and reducing the efficiency of information gathering. It has been found that people may pay less attention to peripheral information, become more disorganized in scanning information, and are more likely to succumb to attentional tunneling when affected by these stressors. People are also more likely to arrive at a decision without taking into account all available information (premature closure).

### 3.4 Data Overload

Data overload is a significant problem in many systems. The volume of data and the rapid rate of change of that data create a need for information intake that quickly outpaces one's ability to gather and assimilate the data. As people can take in and process only a limited amount of information at a time, significant lapses in SA can occur. While it is easy to think of this problem as simply a human limitation, in reality it often occurs because data are processed, stored, and presented ineffectively in many systems. This problem is not just one of volume but also one of bandwidth, the bandwidth provided by a person's sensory and information-processing mechanisms. The rate that data can flow through the pipeline can be increased significantly based on the form of information presentation employed in the interface.

### 3.5 Misplaced Salience

The human perceptual system is more sensitive to certain features than others, including the color red, movement, and flashing lights. Similarly, loud noises, larger shapes, and things that are physically nearer have the advantage of catching a person's attention. These natural salient properties can be used to promote SA or to hinder it. When used carefully, properties such as movement or color can be used to draw attention to critical and highly important information and are thus important tools for designing to enhance SA. Unfortunately, these features are often overused or used inappropriately. The unnecessary distractions of misplaced salience can act to degrade SA of the other information the person is attempting to assimilate. Unfortunately, in many systems there is a proliferation of lights, buzzers, alarms, and other signals that work actively to draw people's attention, frequently either misleading or overwhelming them.

### 3.6 Complexity Creep

Over time, systems have become more and more complex, often through a misguided attempt to add more features or capabilities. Unfortunately, this complexity makes it difficult for people to form sufficient internal representations of how these systems work. The more features and the more complicated and branching the rules that govern a system's behavior, the greater the complexity. Although system complexity can slow down a person's ability to take in information, it works primarily to undermine the person's ability to correctly interpret the information presented and to project what is likely to happen (level 2 and 3 SA). A cue that should indicate one thing can be completely misinterpreted, as the internal mental model will be developed inadequately to encompass the full characteristics of the system.

### 3.7 Errant Mental Models

Mental models are important mechanisms for building and maintaining SA, providing key interpretation mechanisms for information collected. They tell a person how to combine disparate pieces of information, how to interpret the significance of that information, and how to develop reasonable projections of what will happen in the future. If an incomplete mental model is used, however, or if the wrong mental model is relied on for the situation, poor comprehension and projection (level 2 and 3 SA) can result. Also called a *representational*

*error*, it can be very difficult for people to realize that they are working on the basis of an errant mental model and break out of it. Mode errors, in which people misunderstand information because they believe that the system is in one mode when it is really in another, are a special case of this problem.

### 3.8   Out-of-the-Loop Syndrome

Automation creates a final SA demon. While in some cases automation can help SA by eliminating excessive workload, it can also act to lower SA by putting people *out of the loop*. In this state, they develop poor SA as to both how the automation is performing and the state of the elements the automation is supposed to be controlling. When the automation is performing well, being out of the loop may not be a problem, but when the automation fails or, more frequently, reaches situational conditions that it is not equipped to handle, the person is out of the loop and often unable to detect the problem, properly interpret the information presented, and intervene in a timely manner.

## 4   TRAINING TO SUPPORT SITUATION AWARENESS

There is some evidence that some people are significantly better than others at developing SA. In one study of experienced military fighter pilots, Endsley and Bolstad (1994) found a 10-fold difference in SA between the pilot with the lowest SA and the one with the highest SA. They also found this ability to be highly stable, with test–retest reliability rates exceeding 0.94 for those evaluated. Others (Secrist and Hartman, 1993; Bell and Waag, 1995) have similarly noted consistent individual differences, with some pilots routinely having better SA than their compatriots. These individual differences appear even when people operate with the same system capabilities and displays and in the same environment subject to the same demands.

A number of studies have sought to find the locus of these individual differences in SA abilities. Are they due simply to the effects of expertise and experience or are they indicative of the better cognitive mechanisms or capabilities that some people have? Endsley and Bolstad (1994) found that military pilots with better SA were better at attention sharing, pattern matching, spatial abilities, and perceptual speed. O'Hare (1997) also found evidence that elite pilots (defined as consistently superior in gliding competitions) performed better on a divided-attention task purported to measure SA. Gugerty and Tirre (1997) found evidence that people with better SA performed better on measures of working memory, visual processing, temporal processing, and time-sharing ability.

Although these studies have examined individual differences in only a few domains (e.g. piloting and driving), some of these attributes may also be relevant to SA differences in other arenas. If reliable markers can be found that differentiate those who will eventually be most successful at SA, more valid selection batteries can be developed for critical jobs such as air traffic controller, pilot, or military commander.

There has also been research to examine what skills differentiate those with high SA from those with low SA which might be trainable, thus significantly improving SA in the existing population of operators in a domain. For instance, SA differences between those at different levels of expertise have been examined in groups of pilots (Prince and Salas, 1998; Endsley et al., 2000), military officers (Strater et al., 2003), aircraft mechanics (Endsley and Robertson, 2000a), power plant operators (Collier and Folleso, 1995), and drivers (Horswill and McKenna, 2004). These studies have found many systematic differences, some of which may relate to underlying abilities, but many of which also point to learned skills or behaviors that may be trainable.

A number of training programs have been developed that seek to train knowledge and skills related to developing SA (at the individual or team level) in classroom settings, simulated scenarios or case studies, or through computer-based training. These include training programs for commercial aviation pilots (Robinson, 2000; Hormann et al., 2004), general aviation pilots (Prince, 1998; Endsley and Garland, 2000a; Bolstad et al., 2002; Endsley et al., 2002), drivers (Sexton, 1988; McKenna and Crick, 1994), aircraft mechanics (Endsley and Robertson, 2000a,b), and army officers (Strater et al., 2003, 2004). While some of these are classroom-based programs that seek to create more awareness in operators about the concept of SA and the many challenges that effect it, many more detailed programs have been created that seek to build up the critical knowledge and skills that underlie SA.

### 4.1   Interactive Situation Awareness Trainer (ISAT)

ISAT employs rapid experiential learning in support of mental model and schema development. In normal operations, over the course of many months and years, individuals will gradually build up the experience base to develop good mental models and schema for pattern matching upon which SA most often relies. ISAT attempts to boot strap this natural process by exposing the trainee to many, many situations in a very short period of time using computer-based training tools (Strater, et al., 2004). ISAT employs realistic mission scenarios with opportunities for complex operational decisions. It provides an increased opportunity for exposure to a variety of situations which (1) supports the development of situation-based knowledge stores, (2) trains the recognition of critical cues that signal prototypical situations, (3) supports information integration and decision making, and (4) promotes an understanding of the importance of consequences, timing, risk and capabilities associated with different events, behaviors, and decision options. Trainees learn what it means to develop SA in the environment, learn to build higher level SA out of data, and receive training on projecting future events in prototypical situations.

### 4.2   Virtual Environment Situation Awareness Review System (VESARS)

Feedback is critical to the learning process. In order to improve SA, individuals need to receive feedback on the

quality of their SA; however this often is lacking in the real world. For example, inexperienced operators may fail to appreciate the severity of threatening conditions because they have come through similar conditions in the past just by luck. Unfortunately, this also reinforces poor assessments. It is difficult for individuals to develop a good gage of their own SA in normal operations. Training through SA feedback allows trainees to fine tune critical behaviors and mental models based on a review of their SA performance (Endsley, 1989b).

The VESARS approach involves the use of SA measures that assess trainee SA in three areas: (1) a behavioral rating tool that assesses individual and team actions, (2) a communications rating tool that evaluates team communications, and (3) a SA query tool that allows direct and objective assessment of the quality of individual and team SA (Kaber et al., 2005, 2006). VESARS was specifically designed to work well with virtual and simulated training environments but it can also be employed in field exercises. SA training is provided after each simulated trial in which VESARS data are collected. Providing knowledge of results immediately following a simulation on the SA level achieved across the various SA requirements and relevant communications and behaviors allows trainees to understand the degree to which they were able to acquire SA and ways in which they need to modify their processes to improve their SA.

### 4.3 Situation Awareness Virtual Instructor (SAVI)

The SAVI trains warfighters on the behaviors that are consistent with and important to good SA by allowing trainees to play the role of the trainer as they rate the actions of others in vignettes provided through a computer and provide a rationale for their rating (Endsley et al., 2009). The SAVI approach leverages the exponential learning that occurs during peer instruction and in the transition to becoming a trainer. Trainees quickly learn what behaviors are appropriate for various operational situations, because they observe these aspects of performance and provide their assessments on the quality of the performance. Trainees are able to refine their mental models of good SA behaviors and communications as they also compare their assessments to those provided by domain experts. This allows trainees to fine tune their understanding of critical cues and behaviors associated with good SA.

The preliminary findings reported by the majority of these efforts show initial successes in improving SA and performance in their respective settings. In general, more longitudinal studies are needed to ascertain the degree to which such efforts can be successful in improving the SA of persons in the wide variety of challenging situations that are common in these domains.

## 5 SYSTEM DESIGN TO SUPPORT SITUATION AWARENESS

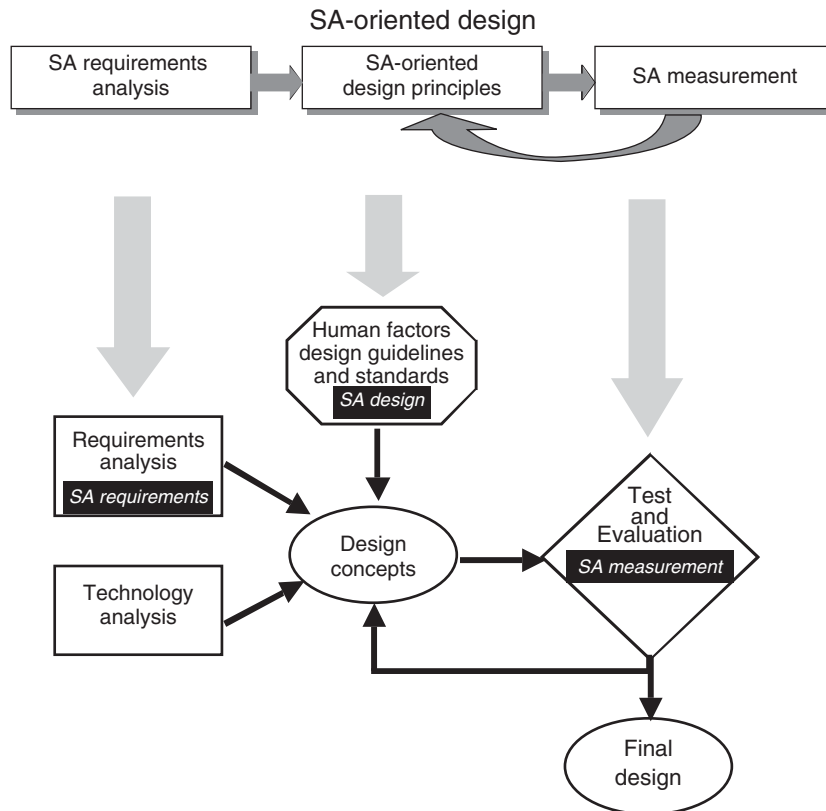
In addition to training to improve SA at the individual level, efforts to improve SA through better sensors,

information processing, and display approaches have characterized much of the past 20 years. Unfortunately, a significant portion of these efforts have stopped short of really addressing SA; instead, they simply add a new sensor or black box that is purported to improve SA. While ensuring that operators have the data needed to meet their level 1 SA requirements is undoubtedly important, a rampant increase in such data may inadvertently hurt SA as much as it helps. Simply increasing the amount of data available to an operator instead adds to the information gap, overloading the operator without necessarily improving the level of SA the person can develop and maintain.

As a construct, however, SA provides a key mechanism for overcoming this data overload. SA specifies how all the data in an environment need to be combined and understood. Therefore, instead of loading the operator down with 100 pieces of miscellaneous data provided in a haphazard fashion, SA requirements provide guidance as to what the real comprehension and projection needs are. Therefore, it provides the system designer with key guidance on how to bring the various pieces of data together to form meaningful integrations and groupings of data that can be absorbed and assimilated easily in time-critical situations. This type of systems integration usually requires very unique combinations of information and portrayals of information that go far beyond the black-box technology-oriented approaches of the past. In the past it was up to the operator to do it all. This task left him or her overloaded and susceptible to missing critical factors. If system designers work to develop systems that support the SA process, however, they can alleviate this bottleneck significantly.

So how should systems be designed to meet the challenge of providing high levels of SA? Over the past decade a significant amount of research has been focused on this topic, developing an initial understanding of the basic mechanisms that are important for SA and the design features that will support those mechanisms. Based on this research, the SA-oriented design process has been established (Endsley et al., 2003) to guide the development of systems that support SA (Figure 4). This structured approach incorporates SA considerations into the design process, including a determination of SA requirements, design principles for SA enhancement, and measurement of SA in design evaluation.

### 5.1 SA Requirements Analysis

The problem of determining what aspects of the situation are important for a particular operator's SA has frequently been approached using a form of cognitive task analysis called *goal-directed task analysis*, illustrated in Figure 5. In such analysis, the major goals of a particular job class are identified, along with the major subgoals necessary for meeting each goal. Associated with each subgoal, the major decisions that need to be made are then identified. The SA needed for making these decisions and carrying out each subgoal are identified. These SA requirements focus not only on what data the operator needs but also on how that information is integrated or combined to address each decision. In this analysis process, SA requirements are defined as


## SA-oriented design

**Figure 4**   SA-oriented design process. (From Endsley et al., 2003.)

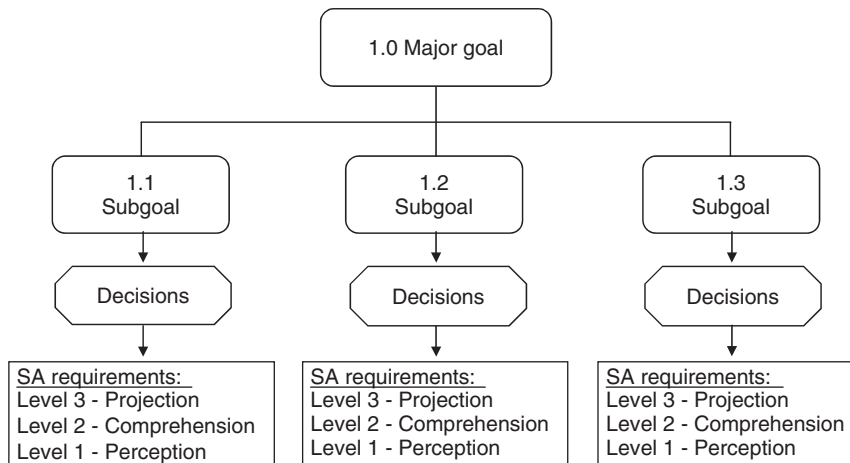


**Figure 5**   Goal-directed task analysis for determining SA requirements.

those dynamic information needs associated with the major goals or subgoals of the operator in performing his or her job (as opposed to more static knowledge, such as rules, procedures, and general system knowledge). This type of analysis is based on goals or objectives, not tasks (as a traditional task analysis might). This is because goals form the basis for decision making in many complex environments. Conducting such an analysis is usually carried out using a combination of cognitive engineering procedures. Expert

elicitation, observation of operator performance of tasks, verbal protocols, analysis of written materials and documentation, and formal questionnaires have formed the basis for the analyses. In general, the analysis has been conducted with a number of operators, who are interviewed, observed, and recorded individually, with the resulting analyses pooled and then validated overall by a larger number of operators.

An example of the output of this process is shown in Table 2. This example shows the SA requirements analysis for the subgoal "maintain aircraft conformance" for the major goal "avoid conflictions" for an air traffic controller. In this example, the subgoal is divided even further into lower level subgoals prior to the decisions and SA requirements being listed. In some cases,

### Table 2  Example of Goal-Directed Task Analysis for En Route Air Traffic Control

1.3 Maintain aircraft conformance

1.3. Assess aircraft conformance to assigned parameters

- Aircraft at/proceeding to assigned altitude?
- Aircraft proceeding to assigned altitude fast enough?
- Time until aircraft reaches assigned altitude
- Amount of altitude deviation
- Climb/descent
- Altitude (current)
- Altitude (assigned)
- Altitude rate of change (ascending/descending)
- Aircraft at/proceeding to assigned airspeed?
- Aircraft proceeding to assigned airspeed fast enough?
- Time until aircraft reaches assigned airspeed
- Amount of airspeed deviation
- Airspeed (indicated)
- Airspeed (assigned)
- Groundspeed
- Aircraft on/proceeding to assigned route?
- Aircraft proceeding to assigned route fast enough?
- Aircraft turning?
- Time until aircraft reaches assigned route/heading
- Amount of route deviation
- Aircraft position (current)
- Aircraft heading (current)
- Route/heading (assigned)
- Aircraft turn rate (current)
- Aircraft heading (current)
- Aircraft heading (past)
- Aircraft turn capabilities
- Aircraft type
- Altitude
- Aircraft groundspeed
- Weather
- Winds (direction, magnitude)

*Source*: Endsley and Rodgers (1994b).

addressing a particular subgoal occurs through reference to another subgoal in other parts of the analysis, such as the need to readdress aircraft separation in this example. This shows the degree to which a particular operator's goals and resultant SA needs may be very interrelated. The example in Table 2 shows just one major subgoal out of four that are relevant for the major goal "avoid conflictions," which is just one of three major goals for an air traffic controller.

This analysis defines systematically the SA requirements (at all three levels of SA) that are needed to effectively make the decisions required by the operator's goals. Many of the same SA requirements appear throughout the analysis. In this manner, the way in which pieces of data are used together and combined to form what the operator really wants to know is determined. Although the analysis will typically include many goals and subgoals, they may all be active at once. In practice, at any given time more than one goal or subgoal may be operational, although they will not always have the same prioritization. The analysis does not indicate any prioritization among the goals (which can vary over time) or that each subgoal within a goal will always be active. Unless particular events are triggered (e.g., the subgoal of assuring aircraft conformance in this example), a subgoal may not be active for a given controller.

The analysis strives to be as technology free as possible. How the information is acquired is not addressed, as this can vary considerably from person to person, from system to system, and from time to time. In some cases it may be through system displays, verbal communications, other operators, or internally generated from within the operator. Many of the higher level SA requirements fall into this category. The way in which information is acquired can vary widely between persons, over time, and between system designs.

The analysis seeks to determine what operators would ideally like to know to meet each goal. It is recognized that they often must operate on the basis of incomplete information and that some desired information may not be available at all with today's system. However, for purposes of design and evaluation of systems, we need to set the yardstick to measure against what they ideally need to know, so that artificial ceiling effects, based on today's technology, are not induced in the process. Finally, it should be noted that static knowledge, such as procedures or rules for performing tasks, is outside the bounds of an SA requirements analysis. The analysis focuses on the dynamic situational information that affects what the operators do.

To date, these analyses have been completed for many domains of common concern, including en route air traffic control (Endsley and Rodgers, 1994b), TRACON air traffic control (Endsley and Jones, 1995), fighter pilots (Endsley, 1993), bomber pilots (Endsley, 1989a), commercial transport pilots (Endsley et al., 1998b), aircraft mechanics (Endsley and Robertson, 1996), and airway facilities maintenance (Endsley and Kiris, 1994). A similar process was employed by Hogg et al. (1993) to determine appropriate queries for a nuclear reactor domain.

## 5.2   SA-Oriented Design Principles

The development of a system design for successfully providing the multitude of SA requirements that exist in complex systems is a significant challenge. Design principles have been developed based on the theoretical model of the mechanisms and processes involved in acquiring and maintaining SA in dynamic complex systems (Endsley, 1988, 1990b, 1995d; Endsley et al., 2003). The 50 design principles include (1) general guidelines for supporting SA, (2) guidelines for coping with automation and complexity, (3) guidelines for the design of alarm systems, (4) guidelines for the presentation of information uncertainty, and (5) guidelines for supporting SA in team operations. Some of the general principles include the following: (1) direct presentation of higher level SA needs (comprehension and projection) is recommended, rather than supplying only low-level data that operators must integrate and interpret manually; (2) goal-oriented information displays should be provided, organized so that the information needed for a particular goal is co-located and answers directly the major decisions associated with the goal; (3) support for global SA is critical, providing an overview of the situation across the operator's goals at all times (with detailed information for goals of current interest) and enabling efficient and timely goal switching and projection; (4) critical cues related to key features of schemata need to be determined and made salient in the interface design (in particular, those cues that will indicate the presence of prototypical situations will be of prime importance and will facilitate goal switching in critical conditions); (5) extraneous information not related to SA needs should be removed (while carefully ensuring that such information is not needed for broader SA needs); and (6) support for parallel processing, such as multimodal displays, should be provided in data-rich environments.

SA-oriented design is applicable to a wide variety of system designs. It has been used successfully as a design philosophy for systems involving remote maintenance operations, medical systems, flexible manufacturing cells, and command and control for distributed teams.

## 5.3   Design Evaluation for SA

Many concepts and technologies are currently being developed and touted as enhancing SA. Prototyping and simulation of new technologies, new displays, and new automation concepts are extremely important for evaluating the actual effects of proposed concepts within the context of the task domain and using domain-knowledgeable subjects. If SA is to be a design objective, it is critical that it be evaluated specifically during the design process. Without this, it will be impossible to tell if a proposed concept actually helps SA, does not affect it, or inadvertently compromises it in some way. A primary benefit of examining system design from the perspective of operator SA is that the impact of design decisions on SA can be assessed objectively as a measure of the quality of the integrated system design when used within the actual challenges of the operational environment.

SA measurement has been approached in a number of ways. See Endsley and Garland (2000b) for details on these methods. A review of the advantages and disadvantages of these methods may be found in Endsley (1996) and Endsley and Smolensky (1998). In general, direct measurement of SA can be very advantageous in providing more sensitivity and diagnosticity in the test and evaluation process. This provides a significant addition to performance measurement and workload measurement in determining the utility of new design concepts. Whereas workload measures provide insight into how hard an operator must work to perform tasks with a new design, SA measurement provides insight into the level of understanding gained from that work.

Direct measurement of SA has generally been approached either through subjective ratings or by objective techniques. Although subjective ratings are simple and easy to administer, research has shown that they correlate poorly with objective SA measures, indicating they more closely capture a person's confidence in his or her SA rather than the actual level or accuracy of that SA (Endsley et al., 1998a).

One of the most widely used objective measures of SA is the SA global assessment technique (SAGAT) (Endsley, 1988, 1995b, 2000a). SAGAT has been used successfully to measure operator SA directly and objectively when evaluating avionics concepts, display designs, and interface technologies (Endsley, 1995b). Using SAGAT, a simulated test scenario employing the design of interest is frozen at randomly selected times, the system displays are blanked, and the simulation is suspended while operators quickly answer questions about their current perceptions of the situation. The questions correspond to their SA requirements as determined from an SA requirements analysis for that domain. Operator perceptions are then compared to the real situation based on simulation computer databases to provide an objective measure of SA.

Multiple "snapshots" of operators' SA can be acquired in this way, providing an index of the quality of SA provided by a particular design. The collection of SA data in this manner provides an objective, unbiased assessment of SA that overcomes the problems incurred when collecting such data after the fact and minimizes biasing of controller SA due to secondary task loading or cuing the controller's attention artificially, which real-time probes may do. By including queries across the full spectrum of an operator's SA requirements, this approach minimizes possible biasing of attention, as subjects cannot prepare for the queries in advance since they could be queried over almost every aspect of the situation to which they would normally attend. The primary disadvantage of this technique involves the temporary halt in the simulation.

The method is not without some costs, however, as a detailed analysis of SA requirements is required in order to develop the battery of queries to be administered. SAGAT is a global tool developed to assess SA across all of its elements based on a comprehensive assessment of operator SA. As a global measure, SAGAT includes queries about all operator SA requirements, including level 1 (perception of data), level 2 (comprehension of

meaning), and level 3 (projection of the near future) components. This includes a consideration of system functioning and status as well as relevant features of the external environment.

SAGAT has also been shown to have predictive validity, with SAGAT scores indicative of pilot performance in a combat simulation (Endsley, 1990a). It is also sensitive to changes in task load and to factors that affect operator attention (Endsley, 2000a), demonstrating construct validity. It has been found to produce high levels of reliability (Endsley and Bolstad, 1994; Collier and Folleso, 1995; Gugerty, 1997). Studies examining the intrusiveness of the freezes to collect SAGAT data have generally found there to be no effect on operator performance (Endsley, 1995a, 2000a)

An example of the use of SAGAT for evaluating the impact of new system concepts may be found in Endsley et al. (1997a). A totally new form of distributing roles and responsibilities between pilots and air traffic controllers was examined. Termed *free flight*, this concept was originally developed as a major change in the operation of the national airspace. It may include pilots filing direct routes to destinations rather than along predefined fixed airways and authority for the pilot to deviate from that route either with air traffic controllers' permission or perhaps even fully autonomously (RTCA, 1995). As it was felt that such changes could have a marked effect on the ability of the controller to keep up as monitor in such a new system, a study was conducted to examine this possibility (Endsley et al., 1997b).

Results showed a trend toward poorer controller performance in detecting and intervening in aircraft separation errors with these changes in the operational concept and poorer subjective ratings of performance. Finding statistically significant changes in separation errors during ATC simulation testing is quite rare, however. More detailed analysis of the SAGAT results provided more diagnostic detail as well as backing up this finding. As shown in Figure 6, controllers were aware of significantly fewer aircraft in the simulation under free-flight conditions. Attending to fewer aircraft under a higher workload has also been found in other studies (Endsley and Rodgers, 1998).

In addition to reduced level 1 SA, however, controllers had a significantly reduced understanding (level 2 SA) of what was happening in the traffic situation, as evidenced by lower SA regarding which aircraft weather would affect the situation and a reduced awareness of those aircraft that were in a transitionary state. They were less aware of which aircraft had not yet completed a clearance and, for those aircraft, whether the instruction was received correctly and whether they were conforming. Controllers also demonstrated lower level 3 SA with free flight. Their knowledge of where the aircraft was going (to the next sector) was significantly lower under free-flight conditions.

These findings were useful in pinpointing whether concerns over this new and very different concept were justified or whether they merely represented resistance to change. The SAGAT results showed not only that the new concept did indeed induce problems for controller SA that would prevent them from performing effectively

**Figure 6**  SAGAT results. (From Endsley et al., 1997b.)

as monitors to back up pilots with separation assistance but also in what ways these problems were manifested. This information is very useful diagnostically in that it allows one to determine what sort of aid might be needed for operators to assist them in overcoming these deficiencies.

For instance, in this example, a display that provides enhanced information on flight paths for aircraft in transitionary states may be recommended as a way of compensating for the lower SA observed. Far from just providing a thumbs-up or thumbs-down input on a concept under evaluation, this rich source of data is very useful in developing iterative design modifications and making trade-off decisions.

## 6  CONCLUSIONS

A firm theoretical foundation has been laid for understanding the factors that affect SA in complex environments. This foundation can be used to guide the development of training programs and the development of system designs that go beyond data presentation to provide higher levels of SA. In either case, validation of the effectiveness of the proposed solutions through detailed, objective testing is paramount to ensuring that the approach is actually successful in improving SA.

The need to process and understand large volumes of data is critical for many endeavors, from the cockpit to military missions, from power plants to automobiles, and from space stations to day-to-day business operations. It is likely that the potential benefits of the information age will not be realized until we come to grips with the challenges of managing this dynamic information base to provide people with the SA they need on a real-time basis. Doing so is the primary challenge of the next decade of technology.

**Kuala Lumpur, Malaysia**

## 1 INTRODUCTION

Recently there has been a rapid growth in affective and pleasurable engineering and design. This development is in great contrast to earlier design traditions in engineering design. The affective and emotive aspects of design have largely been ignored. One exception was Titchener (1910), who considered pleasure an irreducible fundamental component of human emotion.

Design decision making and cognition were considered first by Herbert Simon's (1969) book *The Science of the Artificial*. His expression "The proper study of mankind is the science of design" remains a challenge, since ergonomics has not produced much research in structuring design problems, perhaps because design problems are often ill-defined (Goel and Pirolli, 1992). This presents a challenge also for the present authors because our focus is primarily limited to human factors; we will need to draw on articles published from other fields, and our view may not have been as comprehensive as it could have been.

The term *affect* has different meanings in psychology and human factors. Affect is the general term for the judgmental system, and *emotion* is the conscious experience of affect. Much of human behavior is subconscious, beneath conscious awareness (Leontjev, 1978). Consciousness came late in the evolution of humans and also in the way the brain processes information (Norman, 2005). The affective system makes quick and efficient judgments which help in determining if an environment is dangerous—shall I fight or flight? For instance, I may have an uneasy feeling (affect) about a colleague at work, but I don't understand why, since I am not conscious about what I am reacting to.

*Pleasure*, on the other hand, is a good feeling coming from satisfaction of homeostatic needs like hunger, sex, and bodily comfort (Seligman and Csikszentmihalyi, 2000). This is differentiated from *enjoyment*, which is a good feeling coming from breaking through the limits of homeostasis of people's experiences, for example, performing in an athletic event or playing in a string quartet. Enjoyment could lead to more personal growth and long-term happiness than pleasure, but people usually prefer pleasure over enjoyment, maybe because it is less effortful. Although each discipline has a unique definition, their goals are quite similar. We elaborate further in a later part when we discuss relevant theories of affect and pleasure.

Affective human factors design has a great future because it sells. Examples include affective design of mobile phones (Khalid, 2004; Seva and Helander, 2009) and cars (Khalid et al., 2011). But much more research is needed in this emerging field. Advances in psychology research on affect were elegantly summarized by Kahneman et al. (1999) in their edited volume *Well-Being: Foundations of Hedonic Psychology.* Helander et al. (2001) published the first conference proceedings on affective human factors design. Then Jordan (2002) wrote on pleasurable design while Norman (2005) later wrote on emotional design. In human–computer interaction (HCI), there is the book *Affective Computing* by Picard (1997) and a review by Brave and Nass (2003). *Funology* is a new trend in HCI design (Carroll, 2004; Blythe et al., 2004; Bardzell, 2009). *Hedonomics,* a new term coined by Hancock (2000), has entered human factors engineering (Helander and Tham, 2003; Khalid, 2004; Hancock et al., 2008). Monk et al. (2002) noted that design of seductive and fun interfaces is one important challenge in theory as well as in application.

The expression of emotions is important in product semantics and design. The question of which emotions are invoked naturally follows the question of what the artifact could or would mean to the users (Krippendorff, 2006). In emotional design, pleasure and usability should go hand in hand as well as aesthetics, attractiveness, and beauty (Norman, 2005). The interplay between user-perceived usability (i.e., pragmatic attributes), hedonic attributes (e.g., stimulation, identification), goodness (i.e., satisfaction), and beauty was considered in the design of MP3 player skins (Hassenzahl, 2004, 2010). Hassenzahl found that satisfaction depended on both perceived usability and hedonic attributes.

Jordan (2002) noted that a product or service offering should engage the people for whom it is designed at three abstraction levels: First, it has to be able to perform the task for which it was designed. For example, a car has to be able to take the user from point A to point B. The product's functionality should work well and it should be easy to use. The second level relates to the emotions associated with the product or service. These emotions are part of the "user experience." For example, when using an automated teller machine, feelings of trust and security might be appropriate. Driving a sports car should be exciting, but there should also be a sense of safety. The third level reflects the aspirational or inspirational qualities of the product or service. What does owning the product or using the service say about the user? For example, owning the latest, smallest mobile phone may suggest a "pretty cool" person. These observations make a case for ergonomics as well as for emotional design and social status.

Our premise is that people have affective reactions toward tasks, artifacts, and interfaces. These are caused by design features that operate either through the perceptual system (looking at) or from a sense of controlling (touching and activating) or from reflection and experience. Affective reactions are difficult if not impossible to control; the limbic system in the brain is in operation whether we want it or not. They are in operation whenever we look at objects (beautiful or ugly) and

they are particularly obvious when we try "emotional matching," such as buying clothes for a friend or selecting a birthday card for someone close to us.

Approaches to emotions and affect have been studied with the purpose of understanding (1) how one can measure and analyze human reactions to affective and pleasurable design and (2) how one can produce affective design features of products. Affect is said to be the customer's psychological response to design details of a product, while pleasure is the emotion that accompanies the acquisition or possession of something good or desirable (Demirbilek and Sener, 2003).

Desmet (2003) proposed that products can elicit four categories of emotional responses: instrumental, aesthetic, social, and surprise. *Instrumental emotions* address the use of the product. *Aesthetic emotions* relate to the beauty of a product. *Social emotions* are a result of the product being admired by a group of users. *Surprise emotions* relate to novelty in a design which can amaze users. Each of these emotions results from an appraisal or user experience of a product. With regard to visual perception, this appraisal is based on the aesthetic impressions; the pleasure in using a product will be affected by the pleasure in use; the pleasure of owning the product depends on the importance of the product to the owner. Hence, there are both semantic interpretations of product use (what does it mean to me) and symbolic associations (e.g., pride) that come with ownership (what does my ownership mean to others).

According to Dong et al. (2009), there are three different aspects to consider in affective design: aesthetic impression, semantic interpretation, and symbolic association. *Aesthetic impression* conveys a message about how the product is perceived in terms of attractiveness. This corresponds to Norman's (2005) "visceral level" in design. *Semantic interpretation* relates to what message a product communicates about its function, mode of use, and qualities. This corresponds to Norman's "behavioral level" in design. *Symbolic association* sends a message about the owner or user. It is the personal and social significance attached to the product and its design.

## 1.1 Neurological Basis of Emotions

In the brain the thalamus directs sensory information to the neocortex, which is the thinking part of the brain. The neocortex is the top layer of the cerebral hemispheres. It is 2–4 mm thick and is part of the cerebral cortex. The cortex routes signals to the amygdala (the "emotional brain") for the proper emotional reaction. The amygdala then triggers excretion of peptides and hormones which create emotion and action. However, if there is a potential threat, the thalamus will bypass the cortex and signal directly to the amygdala, which is the trigger point for the primitive fight-or-flight response. When the amygdala feels threatened, it can react irrationally and destructively (Phelps, 2006). Goleman (1995) noted that emotions make us pay attention immediately. There is a sense of urgency and an action plan is prepared without having to think twice. The emotional component evolved very early in the development of mankind. For someone who is being threatened, the

emotional response can take over the rest of the brain in a split second.

The amygdala exhibits three signs: strong emotional reaction, sudden onset, and postepisode realization that the reaction was inappropriate. The soccer player Zinedine Zidane of France head butted Marco Materazzi of Italy in the 2006 World Cup Soccer finals. As a result, France lost the World Cup to Italy and Zidane's career ended in disgrace; his surprising and aggressive response demonstrated the three signs of "amygdala hijack," that is, strong emotional reaction, sudden onset, and regret for your actions when you reflect later. Figure 1 illustrates the neurological mechanisms of the amygdala.

In Figure 1, there are three main areas: the thalamus, the amygdala, and the neocortex. The thalamus receives sensory input from the environment, which is then sent to the cortex for fine analysis. It is also sent to the limbic system, the main location for emotions, where the relevance of the information is determined (LeDoux, 1995). The amygdala evaluates the relevance of much of the information. There are two principal routes to the amygdala (LeDoux, 1993). The most common route passes through the cerebral cortex. The information from the senses will then arrive at the thalamus, and from there it goes to the corresponding primary sensory cortex, which will extract auditory, visual, and tactile information. The stimulus is then elaborated in different parts of the associative cortex, where complex characteristics and global properties are analyzed. The results are sent to the amygdala, as well as to the areas associated with the hippocampus, which is a neighboring structure to the amygdala and communicates directly with the amygdala. As the amygdala receives this information, it will evaluate the desirability or danger of the stimulus. For example, the sight of a tiger at close quarters is a highly alarming stimulus if we are in the jungle but completely harmless if it is in a cage at

the zoo. This context-related information appears to be provided by the hippocampus.

The limbic system coordinates the physiological response and directs the attention (in the cortex) and various cognitive functions. Primitive emotions (e.g., the startle effect) are handled directly through the thalamus–limbic pathway. In this case the physiological responses are mobilized, such as for fight and flight. Reflective emotions, such as pondering over a beautiful painting, are handled by the cortex. In this case physiological responses are not necessary; the situation is harmless and there is no requirement to deal any further with the situation. According to Kubovy (1999), these types of *pleasures of the mind* do not give rise to a physiological response or to any facial expressions.

## 1.2 Affective Design

"The reptilian always wins" (Rapaille, 2006). An object with a strong identity—good quality, design and functionality—makes a reptilian. However, many affective needs are unspoken and need to be identified by probing user emotions. To increase a product's competitiveness, emotions are incorporated into design (Helander and Khalid, 2006).

Designers are expanding the semantic approach to design by utilizing affective design parameters. By so doing, objects take on meanings that were previously not present. Indeed, semantic design prescribes that objects should have a meaning that goes beyond their functional outlook (Krippendorff, 2006). Designers need to identify components of affective as well as functional design and integrate these components in product design. Functional requirements are easy to understand, but affective requirements are subtle and puzzling and often difficult to identify. They vary over time, and customers often have difficulties in explaining

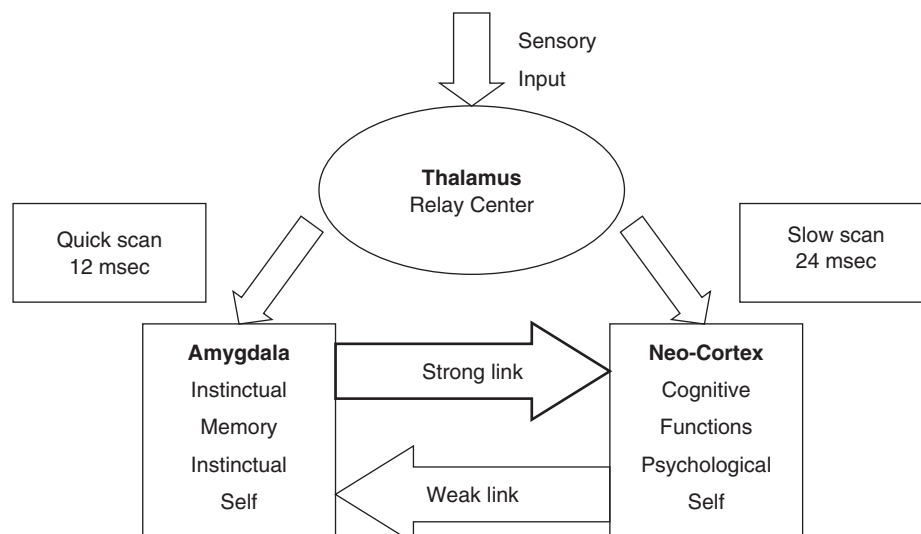

**Figure 1** Role of amygdala.

what the requirements are (Khalid et al., 2011). With the growing emphasis on emotional design, some companies have created design which may not directly cater to customer needs but rather support the company's standing as a premier design house. Hence, there are many reasons for affective design.

## 1.3 Integration of Affective and Cognitive Systems

Cognition must consider affect or emotion and vice versa; human decision making and behavior are guided by cognition as well as emotions. Figure 2 denotes the relationship between affect and cognition. Whereas affect refers to feeling responses, cognition is used to interpret, make sense of, and understand user experience. To do so, symbolic, subjective concepts are created that represent the personal interpretations of the stimuli. Cognitive interpretations may include a deeper, symbolic understanding of products and behaviors.

One of the most important accounts of affect in decision making comes from Damasio (1994). In his book *Descartes' Error*, he described observations of patients with damage to the ventromedial frontal cortex of the brain. This left their intelligence and memory intact but impaired their emotional assessments. The patients were socially incompetent, although their intellect and ability to analyze and reason about solutions worked well. Damasio argued that thought is largely made up from a mix of images, sounds, smells, words, and visual impressions. During a lifetime of learning, these become "marked" with affective information—positive or negative feelings. These *somatic markers* are helpful in predicting decision making and behavior.

Affect plays a central role in dual-process theories of thinking, knowing, and information processing (Epstein, 1994). There is hence much evidence that people perceive reality in at least two ways; one is affective (intuitive and experiential) and the other is cognitive (analytical and rational). Formal decision making must consider a combination of affective and cognitive factors; the affective system is much quicker than the cognitive system. When a person seeks to respond to an emotional event, he or she will search the affective system automatically for past experiences. This is like searching a memory bank for related events, including their emotional contents (Epstein, 1994), see Figure 3.

Emotions do not cause thinking to be nonrational; they can motivate a passionate concern for objectivity, such as anger at injustice. There is a cross-coupling so that rational thinking facts as well as feelings and affective thinking entail cognition. Rational thinking is perhaps more precise, comprehensive, and insightful than nonrational thinking. However, it is just as emotional.

Separating emotion from cognition has been considered a major weakness of psychology and cognitive science (Vygotsky, 1962). Recent research using functional magnetic resonance imaging (fMRI) has validated the assertions that cognition and emotions are at least partly unified and contribute to the control of thought and behavior (Vul et al., 2009). William James wrote about this already in the 1890s. However, there are some exceptions. If a person is facing fear, the bodily reaction may come first, for example in a tsunami disaster (Khalid et al., 2010). The person will start running instinctively before there is any cognitive evaluation. The order of response would be (1) affect, (2) behavior, and (3) cognition.

Cognition also contributes to the regulation of emotion. Contemporary views in artificial intelligence and psychology are embracing an integrated view of emotion and cognition. In *Emotion Machine*, Minsky (2007) noted that the traditional idea that ''thinking" is contaminated by "emotions" is not correct. He claimed that emotions and thinking cannot be separated; they are unified.

Combining the description from contemporary psychology and neuroscience, Camerer et al. (2005) illustrated the two distinctions between controlled and automatic processes (Schneider and Shiffrin, 1977) and between cognition and affect, as in Table 1.

As described in Table 1, controlled processes have several characteristics. They tend to (1) be serial (employing a step-by-step logic or computations); (2) be invoked deliberately by an agent when encountering a challenge or surprise; (3) be associated with a subjective feeling of effort; and (4) typically occur consciously. As such, people have reasonably good introspective access

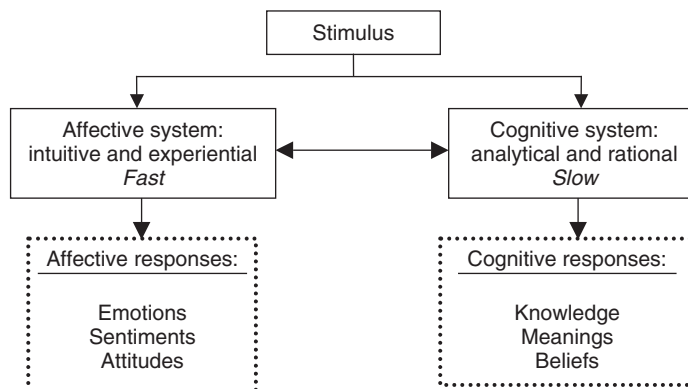

**Figure 2**　Integration of affect and cognition.
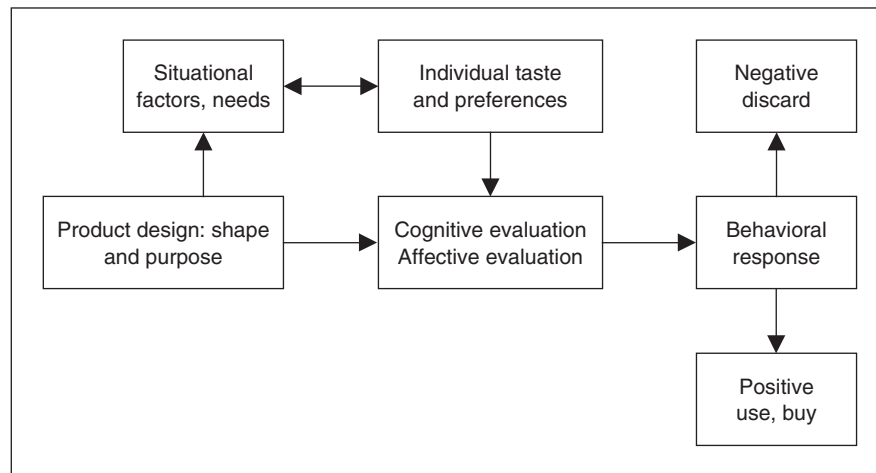

**Figure 3** Comparison and evaluation of product shape and individual preferences.

**Table 1  Two-Dimensional Characterization of Neural Functioning**

| Type of Process | Cognitive | Affective |
|---|---|---|
| Controlled Processes<br>• Serial<br>• Evoked deliberately<br>• Effortful<br>• Occurs consciously | I | II |
| Automatic Processes<br>• Parallel<br>• Effortless<br>• Reflexive<br>• No introspective access | III | IV |

*Source*: Camerer et al. (2005)

to controlled processes. If they are asked how they solved a math problem or chose a new car, they can usually provide a good account of the decision-making process.

Automatic processes are the opposite of controlled processes. Automatic processes tend to (1) operate in parallel; (2) not be associated with any subjective feeling of effort; and (3) operate outside of conscious awareness. As a result, people often have little introspective access as to why the automatic choices or judgments were made. For example, a product can be perceived automatically and effortlessly as "attractive"; it is only in retrospect that the controlled system may reflect on the judgments and try to substantiate it logically.

The second distinction, represented by the two columns of Table 1, is between cognitive and affective processes. This distinction is pervasive in psychology (e.g., Zajonc, 1998) and neuroscience (Damasio, 1994; LeDoux, 1995). Zajonc (1998) defined *cognitive processes* as those that answer true–false questions and *affective processes* as those that motivate approach–avoidance behavior. Affective processes

include emotions, such as anger, sadness, and shame, as well as "biological affects" such as hunger, pain, and the sex drive (Buck, 1999).

Elaborating this further, quadrant I, for example, is in charge when one considers purchase of an expensive machine. Quadrant II can be used by "actors," such as salespersons, who replay previous emotional experiences to motivate customers that they are experiencing these emotions. Quadrant III deals with motor control and governs the movements of the limbs, such as a tennis player when he or she returns a serve. Quadrant IV applies when a person wins a surprising award. The four categories are often not so easy to distinguish because most behavior results from a combination of several quadrants.

## 1.4  Understanding Affect and Pleasure in Different Disciplines

There are many definitions and classifications of affect and pleasure in the literature. We mention a few that have relevance to human factors design.

***Marketing***  Peter and Olson (1996), with a background in marketing, defined four different types of affective responses: *emotions, feelings, moods,* and *evaluations*, and offered a classification (Table 2). These responses are associated with different levels of physiological arousal as well as different intensities of feeling. Emotions are associated with physiological arousal, while evaluations (e.g., reflections) of products typically encompass weak affective responses with low level of arousal.

***Product Design***  Tiger (1992) identified four conceptually distinct types of pleasure from a product. These were further elaborated by Jordan (see Blythe, et al. 2003). We extended the taxonomy to five. Whether they are used as a source for pleasure depends on the needs of the individual.

**Table 2  Types of Affective Responses**

| Type of Affective Response | Examples of Positive and Negative Affect | Level of Physiological Arousal | Intensity or Strength of Feeling |
|---|---|---|---|
| Emotions | Joy, love<br>Fear, guilt, anger | Higher arousal and activation | Stronger |
| Specific feelings | Warmth, appreciation,<br>Disgust, sadness | | |
| Moods | Alert, relaxed, calm<br>Blue, listless, bored | | |
| Evaluations | Like, good, favorable<br>Dislike, bad, unfavorable | Lower arousal and activation | Weaker |

*Source*: Peter and Olson (1996)

- *Physical or physio-pleasure* has to do with the body and the senses. It includes things like feeling good physically (e.g., eating, drinking), pleasure from relief (e.g., sneezing, sex), as well as sensual pleasures (e.g., touching a pleasant surface).

- *Socio-pleasures* include social interaction with family, friends, and co-workers. This includes the way we are perceived by others, our persona, and our status.

- *Psychological pleasure* has to do with pleasures of the mind—reflective as well as emotional. It may come from doing things that interest and engage us (e.g., playing in an orchestra or listening to a concert), including being creative (e.g., painting) or enjoying the creativity of other people.

- *Reflective pleasure* has to do with reflection on our knowledge and experiences. The value of many products comes from this and includes aesthetics and quality.

- *Normative pleasure* has to do with societal values such as moral judgment, caring for the environment, and religious beliefs. These can make us feel better about ourselves when we act in line with the expectation of others as well as our beliefs.

Jordan (1998) defined pleasure with products as the emotional and hedonic *benefits* associated with product use. Coelho and Dahlman (2000) defined displeasure as the emotional and hedonic *penalties* associated with product use. Chair comfort, for example, has to do with feeling relaxed, whereas chair discomfort has to do with poor biomechanics. The two entities should be measured on different scales as they are two different dimensions (Helander and Zhang, 1997). Both discomfort and displeasure operate like design constraints; we know what to avoid but that does not mean we understand how to design a pleasurable product. Fixing poor biomechanics

and getting rid of displeasure do not necessarily generate a sense of relaxation and comfort.

With increasing age and personal experiences, our repertoire of emotions expands. Researchers believe that only the startle reflex is innate, while most emotions are learned over time, especially sentiments. People are often attracted to complexity in music and in art. One can listen to a piece of music many times; each time one discovers something new. Likewise in a painting; many modern paintings are difficult to comprehend—each time you look, the interpretation changes. Some pleasures are hard to appreciate, and therefore they become challenging.

## 2  FRAMEWORK FOR AFFECTIVE DESIGN

Design is a problem-solving discipline. Design addresses not only the appearance of the designed product but also the underlying structure of the solution and its anticipated reception by users. A design theory helps designers to identify the problem and develop their "instincts" in selecting the right solutions (Cross, 2000).

A product design represents a solution to a set of design goals and constraints which are formulated by the designer. The design constraints include performance objectives constraints, ergonomic constraints, product and cost constraints, and regulatory and legal constraints (Ullman, 2009).

### 2.1  How Designers Design

Crilly et al. (2009) interviewed 21 UK-based industrial designers with significant professional experience and they also held senior design positions. The purpose was to investigate the goals and procedures that drive designers of products. The outcome of the research is summarized in Table 3. Clearly, a designer's choice of strategies would depend on the type of product and customer requirements. For example, in emotional design, designers elicit emotional responses in consumers by designing products that surprise, satisfy, or delight.

**Table 3  Design Strategies among Product Designers**

| Stages | Strategies |
| --- | --- |
| 1. Attention | Draw consumer attention away from other alternatives. |
| 2. Recognition | Incorporate product brand, tradition, and style since consumers recognize this. |
| 3. Attraction | Make product attractive/elegant. There are no formulas. It is solely intuitive design. |
| 4. Comprehension | Improve usability by using product form to inform customers how it should be used or how it works. |
| 5. Attribution | Carefully manipulate product form to enhance impressions of usability and reliability. |
| 6. Identification | Generate forms that imply lifestyles. |
| 7. Emotion | Elicit emotional responses in consumers by designing products that surprise, satisfy, or delight. |
| 8. Action | Encourage purchase and usage behaviors which promote consumer satisfaction and commercial success. For example, buy and then frequently update a model for children's toothbrush. |

*Source*: Crilly et al. (2009).

Until recently, the affective aspects of design and design cognition were substantially absent from formal theories of design. However, as Rosenberg and Hovland (1960) noted 50 years ago, affect is a prerequisite to the formation of human beliefs, values, and judgments, and design models that do not include affect (emotions, feelings) are inadequate.

Much of the ability to render attractive products is attributed to the personal experiences and creativity of designers. It is a question of making the design as simple and as clean and aesthetic as possible; much hard work goes into creating a clean image.

A product design represents a solution to a set of design goals and constraints which are realized by the designer (Bloch, 1995), as mentioned above.

## 2.2  Consumer Process

The process of buying a product is influenced by two affective processes: (1) affective matching of needs and (2) affective matching of personal utility; see Figure 4.

In the first instance a person tries to match features of several alternative products to his or her perceived needs. At the same time the customer has constraints that eliminate many products due to price, suitability, and aesthetics design. Assume that you are buying a shirt or a blouse for a friend. You will consider the price, size, style, and color. You will try to imagine how well it fits to his or her personal needs and if the shirt will be appreciated. This "emotional matching" also occurs when you buy a shirt or a blouse for yourself, except that the process is more automatic, and you may not consciously reflect on all the details. So, the personal evaluation process is quicker and sometimes subconscious. While you are aware of why you like something, you may not have reflected on why you reject an item. Consider, for example, going through a rack of blouses or shirts in a store. The rejection of an item takes only a second. The affective matching of a blouse is a pattern-matching process with well-developed criteria

for aesthetics and suitability. The constraint filter helps in decision making by eliminating alternatives. It operates in a similar fashion to the decision heuristic "elimination by aspect" (Tversky, 1972). Some blouses are rejected at an early stage. This can happen for many reasons, such as high price, ugly color, and poor quality. A quick decision is then made to reject the product and consider the next (Seva and Helander, 2009).

If the blouse is accepted, there will be a trial adoption. A customer may try the blouse. A second affective matching takes place, where the personal utility and the benefit–cost ratio of the purchase are judged. There can be three decision outcomes: reject (search for another blouse), accept (pay and leave), or give up (walk out of the store).

Based on the sales pattern and customer surveys, the product mix in a store will be modified. However, for a new product, it may not be possible to predict customer emotions and the sales. Below we focus on methods for measuring emotion response to artifacts, an important factor in determining the success of a product.

## 2.3  Affective User–Designer Model

Taking the designer and consumer into consideration, the systems model in Figure 5 provides a framework for issues that must be addressed in affective engineering and design (Helander et al., 2010), based on a novel concept called *citarasa*.

*Citarasa* originated from Sanskrit; the term is widely used in regions where the Malay language is spoken. The word *Cita* means "intent, aspiration," while *Rasa* means "feelings, taste" (Khalid, 2006). Citarasa presupposes that people have an *emotional intent*, that is, an explicit goal-driven desire, when they want a product, and design must therefore address customers' emotional intent and affective needs.

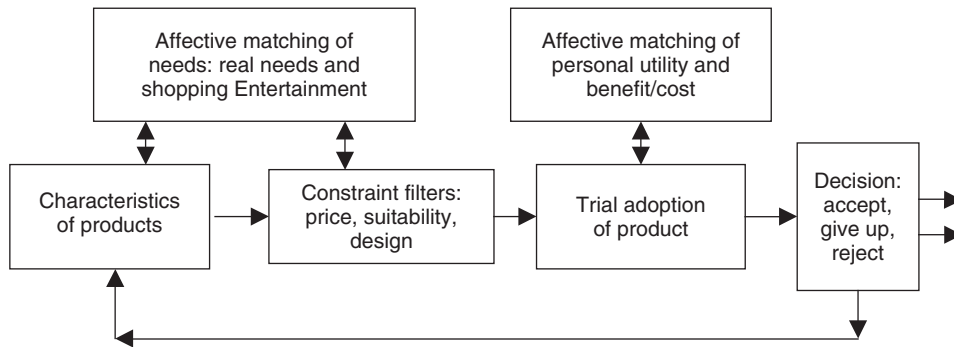
To conceptualize the framework, we used Khoo's (2007) investigation of how emotional intent developed when a person bought a new car. First, he made contacts


**Figure 4** Consumer process.

with car buyers in a showroom in Singapore. Using cognitive task analysis (Crandall et al., 2006), he probed their reasons for buying a car to identify tacit information such as buyer expertise. Each customer was interviewed several times during a six-month period in three stages:

- *Stage* 1. Initially, a customer maintains beliefs about different cars. This stage deals primarily with *affective requirements*. A customer first talks to his friends and reads technical reviews and literature about cars. He may consider the "dream car" (such as a Porsche) but soon realizes that this would be unrealistic.

- *Stage* 2. About six months before the purchase he visits showrooms and test drives cars. This is where the researchers made contacts with the customers. During this stage customers talk to their family about functional needs—what the car will be used for, how many persons travel, fuel consumption, and anticipated repair record. This stage basically deals with *functional requirements*.

- *Stage* 3. Just before making the purchase, the buyer will consider the "quality" of the car, and several customers upgraded their purchase to a car with higher price in order to improve quality. However, the higher price also brings greater prestige, and it was difficult to distinguish which of the two motives inspired the car buyer. This stage combines affective and functional requirements.

During this period customers went through motivational stages, following the model by Fishbein and Ajzen (1975): from belief (about personal needs including luxury) to attitude (personal preferences) to intention (sorting out the real needs of the family) to behavior (purchase).

With this information we developed a model of emotional intent as shown in Figure 5. To investigate intent we identified customers' functional and affective requirements when buying a product such as a car. A need for an "elegant" car can relate to several interior or exterior characteristics, such as color, shape, size, and capacity that can be manipulated by designers to satisfy customer needs.

Citarasa descriptors were generated from the visceral, behavioral, and reflective needs of the customer (Norman, 2005; Helander and Khalid, 2009). The needs were elicited by probing the customer's intent using a laddering technique called the why-why-why interview method (Goh, 2008; Helander et al., in press; Khalid et al., 2011).

In Figure 5, there are two subsystems: the designer environment (for product development) and the customer/user environment (for evaluation of functional and affective design factors).

***Designer Environment***   In designing a new vehicle, a product planner/designer uses information from a variety of sources, including *marketing, context of use/activity* of a vehicle, and *society norms and fashions*. This information broadly determines the design goals (what one should design) and the constraints (what one should not design). The Marketing Department will offer information about customer needs and future markets which will determine design goals. In addition, Marketing will often determine economic parameters, including the sales price, thereby imposing important design goals and constraints.

Affect is elicited not only by perceptual features of the product but also by the activity with the product and context of use. Hence, product planners must analyze the context of activity, that is, primarily driving. This will determine not only affective requirements but also implicitly functional requirements of the vehicle. Some design factors are influenced by social norms and fashions. For example, functional requirements concerning fuel efficiency will be regulated by governments as well as by customers. After they are adopted by Marketing, they appear to the designer as design constraints. Trends and fashions in design are important and play a decisive role in affective design.

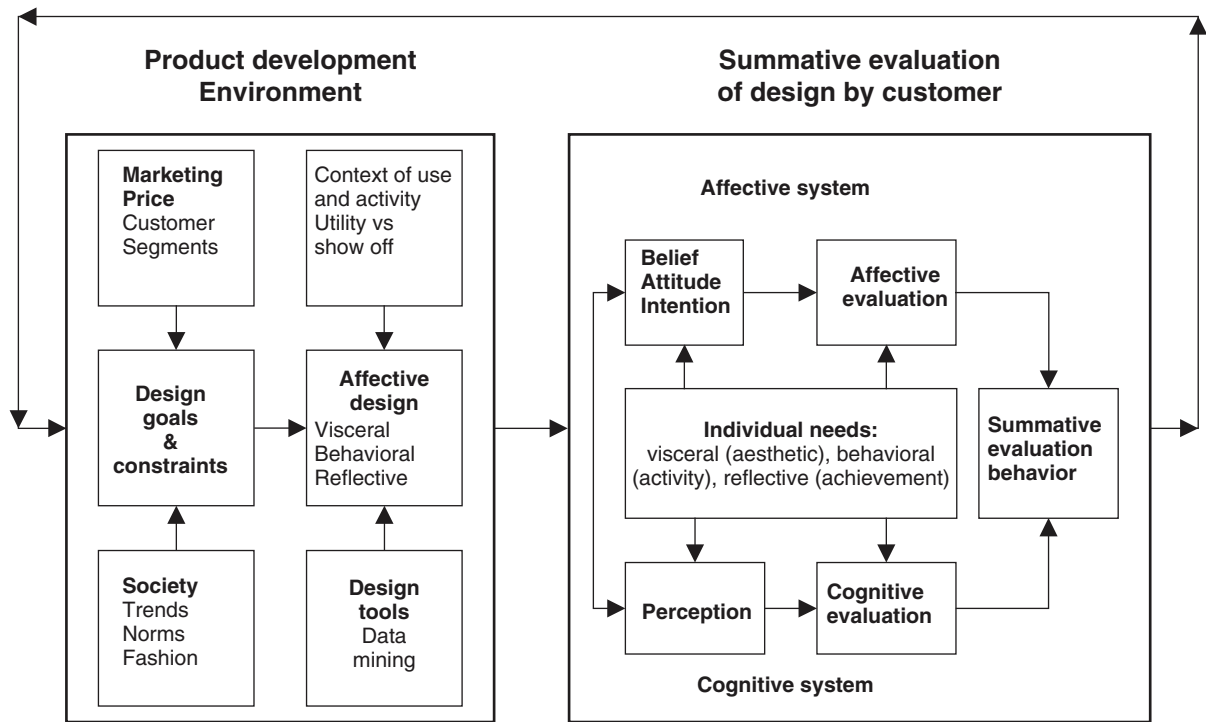
Product planners and designers need to understand how affective design can be derived. Norman (2005) noted that there are three types of affective design features—visceral, behavioral, and reflective:


**Figure 5**   Framework for evaluation of affective engineering and design (Helander and Khalid, 2009).

- *Visceral design* refers to the visual aspects of the design, such as shape, color, materials, ornamentation, and texture. Visceral design is applied to many designed objects with aesthetic value. For vehicle design, there are several basic factors, including the vehicle exterior and interior and elements such as dashboard, seats, and controls. The information on affective needs of buyers is then translated into affective and functional requirements by designers.

- *Behavioral design* has to do with the pleasure in using the object, such as steering a smooth and well-balanced vehicle, driving at a very high speed, and intuitively finding controls. Steering a vehicle with a well-designed steering system along a curvy road can similarly be very satisfying.

- *Reflective design* has to do with things that have been learned over the years. A vehicle buyer may take much interest in an aesthetic design, because it was a tradition in the family to be surrounded by beautiful objects from early childhood. The interest and preferences for aesthetic design are learned and will typically increase with age (Norman, 2005).

There are also cultural differences in learned preferences, for example, Chinese will buy red items because it symbolizes happiness, while Indians associate red with power and strength (Helander et al., 2007; Chang et al., 2006). Designers should consider first-hand customer's conscious reflective needs, which would comply with the current fashion trends and a person's cultural background. Reflective design assumes that the emotional intent (affective requirements) drive customer choice, together with functional requirements. Customers reflect on the suitability of various design options and select a vehicle that suits both types of requirements.

Design features of a car will be addressed by the designer one by one, whereas the customer uses a holistic evaluation—for example, "I like it" without reflecting on what exactly triggered this reaction. It is important that designers are well informed about these different and complementary design options and understand how to implement them. This will require training, so that designers can make conscious decisions and fully understand when and how to utilize visceral, behavioral, and reflective design.

***Customer/User Environment***  This subsystem is made up of a user's affective and cognitive systems. The affective system is based on the capability of the product to elicit affect. Due to uniqueness in style and personality some products are more capable of evoking affect than others (Seva and Helander, 2009). The prospect of owning such a product generates a variety of emotions that are not experienced when confronted with standardized products. In essence, deep-seated desires of users for individuality, pleasure, and aesthetics cause emotion in a user's evaluation of the product.

Products also elicit cognitive responses, appraised according to fulfillment of identified functions. For example, a car must not only be capable of transportation but must also be reliable. In the process of evaluation, the user employs previous knowledge to determine if the product is acceptable to one's standard or not. There are very clear criteria that have been set forth by the user that can be rationally measured to arrive at a decision. The cognitive system shown in Figure 5 follows the human information-processing model that explains the psychological processes involved in interacting with a system. The system begins with the perception of the artifact's attributes. The attributes trigger cognition and memory recall. Information stored in memory about a product is retrieved and used for evaluation and decision making. When evaluating a car, for example, knowledge obtained from past experiences, published material, and other customers' opinion come to mind and are used to make the best decision. The decision is then used as a basis for one's action—to make or forego a purchase.

Customers' individual needs influence information processing. A person's attention is attracted by visual items that stand out because of color, brightness, and size (Triesman and Souther, 1985). Attention is also drawn by unique design features that lead customers to feel awe, surprise, and excitement. Emotions are experienced because some needs are fulfilled just by the sight of a product or the prospect of owning it. Visual aesthetics affect the consumer's perception of a product in many ways and influence the evaluation of a product (Bloch et al., 2003). Like aesthetics, achievement drives people's emotion and influence perception. People feel pleasure at the thought of accomplishing something worthy (Kubovy, 1999). The need for achievement is comparable to the need to satisfy one's curiosity by gathering more information. A customer who wants to buy a car or a truck suddenly becomes aware of the models and brands that are available when he or she had been oblivious of this information in the past.

The need for power can draw a person to products that can enhance his or her image. Color is one product attribute that elicits strong emotion and association (Chang et al., 2006). It may communicate complex information and symbolism as well as simple messages. Automobile design is an area where color seems to have fairly consistent associations. In Western countries, black is a color associated with status and sophistication. We found black to be associated with "elegance" in Europe as well as Asia (Khalid et al., 2011).

To summarize, pleasure with products is viewed from three theory-based perspectives: (1) the context of use and activity; (2) categories of pleasure with products, including visceral, behavioral, and reflective; and (3) the centrality of human needs structure in driving both the cognitive and affective evaluation systems. With reference to Figure 5, pleasure with products should be considered in the context of product use—the activity context. The same product can bring forth different levels of pleasure, depending on the goals and expectations of the user and the activity that is being performed.

Users' requirements of designed products have frequently been compared to Maslow's hierarchy of needs. This suggests that, once issues of utility, safety, and

comfort have been satisfied, emphasis may shift toward the decorative, emotional, and symbolic attributes of design (Yalch and Brunel, 1996). Therefore, depending on motivation and context, a product's perceived attributes may be of greater importance than what its actual performance would suggest. This is because appearance is important; consumers do not just buy a product, they buy value in the form of entertainment, experience, and identity.

## 3 THEORIES OF AFFECT AND PLEASURE

Several theories in psychology support the notions that we have raised, while some provide directions for future research and methods development. These theories are summarized below.

### 3.1 Activity Theory

Activity theory employs a set of basic principles and tools—object orientedness, dual concepts of internalization/externalization, tool mediation, hierarchical structure of activity, and continuous development—which together constitute a general conceptual system (Bannon, 1993). In human activity theory, the basic unit of analysis is human (work) activity. Human activities are driven by certain needs, where people wish to achieve a certain purpose (Bannon and Bødker, 1991). The activities are usually mediated by one or more instruments or tools, such as a photographer using a camera. Thus, the concept of mediation is central to activity theory.

Leontjev (1978) distinguished between three different types of cognitive activities: (1) simple activity, which corresponds to automated stimulus–response; (2) operational activity, which entails perception and an adaptation to the existing conditions; and (3) intellectual activity, which makes it possible to evaluate and consider alternative activities. Note that these activities are in agreement with Rasmussen's model of skill-based, rule-based, and knowledge-based behavior (Rasmussen et al., 1994). For each of the cognitive stages there are corresponding emotional expressions: affect, emotion, and sentiments.

*Affect* is an intensive and relatively short-lasting emotional state. For instance, as I walk down colorful Orchard Road in Singapore and look at items displayed in the shop windows, there are instantaneous reactions to the displayed items, most of these reactions are unconscious, and I have no recollection of them afterward. Through affect, we can monitor routine events. Many events are purely perceptual and do not require decision making, but there is an affective matching of events that are stored in memory (see Figure 4). This helps in understanding and interpreting their significance.

*Emotions* are conscious. When I stop to look at some item in one of the shopping windows, I am aware of why I stopped. Emotions go beyond the single situation and typically remain in memory for one or several days.

*Sentiments* according to Leontjev (1978) are longer lasting and include intellectual and aesthetic sentiments, which also affect my excursion along Orchard Road. I know from experience that some stores are impossible;

on the other hand, there are a few that are clearly very interesting. Sentiments are learned responses.

Feelings are an integral aspect of human activity and must be investigated as psychological processes that emerge in a person's interaction with his or her objective world. Their processes and states guide people toward achieving their goals (Aboulafia and Bannon, 2004). Feelings should not be viewed merely as perturbances of underlying cognitive processes. Predicting affect is likely to be easier than predicting emotions or sentiments. To evoke affective reactions in a user, the artifact could be designed to provide people with a variety of sudden and unexpected changes (visual or auditory) that cause excitement and joy or alarm. Designing toys for children can give us ideas about such design space.

Predicting emotional responses that extend over several situations can be more difficult. Emotions are not dependent on the immediate perceptual situation. The emotional state of a computer user is not usually oriented toward the mediating device itself but to the overall activity in general (either work activity or pleasure). The artifact is merely a mediating tool between the motive and the goal of the user (Aboulafia and Bannon, 2004).

Leontjev (1978) emphasized that emotions are relevant to activity, not to the actions or operations that realize it. In other words, several work or pleasure situations influence the emotion of the user. Even a successful accomplishment of one action or another does not always lead to positive emotions. For example, the act of sneezing in itself usually evokes satisfaction. However, it may also evoke fear of infecting another person. Thus, the affective and emotional aspects of objects are capable of changing, depending on the nature of the human activity (the overall motive and goal). As such, stressed Aboulafia and Bannon (2004, p. 12), "objects or artifacts—in and of themselves—should not be seen as affective, just as objects in and of themselves should not be defined as 'cognitive' artifacts, in Norman's (1991) sense. The relation between the object (the artifact) and the human is influenced by the motive and the goal of the user, and hereby the meaning or personal sense of the action and operation that realize the activity."

We note that Norman (2005) would object to these notions. In fact, he proposed that domestic robots need affect in order to make complex decisions, and Velásquez (1998) wrote about robots that weep. Equipped with only pure logical functions, a robot would not be able to make decisions—just like Damasio's (1994) patients.

### 3.2 Emotions versus Pleasures of the Mind

Ekman (1992, 1994) stated that there are five fundamental emotions that differ from one another in important ways: anger, fear, sadness, disgust, and happiness. Evolution played an important role in shaping the features of these emotions as well as their current function.

The pleasures of the mind have been neglected by contemporary psychology (Cabanac, 1992). Kubovy (1999) argued that pleasures of the mind are different from basic emotions. Pleasures of the mind are not accompanied by any distinctive facial expression. Take, for example, a person viewing a painting in a museum.

She may feel elated, but nothing is revealed on her face, and there is no distinctive physiological response pattern. This is very different from social interaction, such as a conversation with a colleague at work, where half of the message is in the person's face. Since one may not be able to use either physiological measures or facial expressions, one is left with subjective measures. There is nothing wrong with asking people; subjective methods, interviews, questionnaires, and verbal protocols provide valuable information. The problem is what questions should be asked in order to differentiate between products?

The notion of pleasures of the mind dates back to Epicurus (341–270 B.C.), who regarded pleasures of the mind as superior to pleasures of the body because they were more varied and durable. Kubovy (1999) also noted that pleasures of the mind are quite different from pleasures of the body, for example, tonic pleasures and relief pleasures. Table 4 summarizes Ekman's eight features of emotion in the left-hand column; the right-hand column shows pleasures of the mind.

### 3.3 Reversal Theory: Relationship between Arousal and Hedonic Tone

Arousal is a general drive which has its roots in the central nervous system. According to common arousal theories, organisms fluctuate slightly about a single reference point. Reversal theory, on the other hand, focuses on the subjective experiences of humans. The central concept of reversal theory is that the preferred arousal level fluctuates (Apter, 1989). Reversal theory claims that people have two preferred points, and they

**Table 4  Features of Emotions and Pleasures of the Mind**

| Emotions . . . | Pleasures of the mind . . . |
| --- | --- |
| Have a distinctive universal signal (such as a facial expression) | Do not have a distinctive universal (facial) signal |
| Are almost all present in other primates | At least some of them may be present in other primates |
| Are accompanied by a distinctive physiological response | Are not accompanied by a distinctive physiological response |
| Give rise to coherent responses in the autonomic and expressive systems | Do not give rise to coherent responses |
| Can develop rapidly and may happen before one is aware of them | Are relatively extended in time |
| Are of brief duration (on the order of seconds) | Are usually not of brief duration |
| Are quick and brief and imply the existence of an automatic appraisal mechanism | Even though neither quick nor brief, may be generated by an automatic appraisal mechanism |

*Source*: Kubovy (1999, p. 137)

frequently switch or reverse between them. The theory therefore posits bistability rather than homeostasis. In the first state, which is called *telic*, low arousal is preferred, whereas high arousal is experienced as unpleasant. In the telic state, calmness (low arousal, pleasant) is contrasted with anxiety (high arousal, unpleasant). The opposite is true when the person is in the *paratelic* state. In the paratelic state, low arousal is experienced as boredom (unpleasant) and high arousal as excitement (pleasant).

A given level of arousal may therefore be experienced as either positive or negative. A quiet Sunday afternoon can be experienced as serene or dull. One may also experience a crowded and noisy party as exciting or anxiety provoking. The perceived level of pleasantness, called *hedonic tone*, is different for the two states. The paratelic state is an arousal-seeking state and the telic state arousal avoiding. When in the telic state, people are goal oriented; they are serious minded and try to finish their current activity to attain their goal. On the other hand, to have a good time, the paratelic state is appropriate. Goals and achievements are not of interest; rather, this is the time to play, have fun, and be spontaneous.

### 3.4 Theory of Flow

*Flow* is a state of optimal experience, concentration, deep enjoyment, and total absorption in an activity (Csikszentmihalyi, 1997). Csikszentmihalyi (1990) described that when people become totally absorbed by an activity time flies quickly. They forget other things around them and focus on the activity. He referred to this as the state of flow. Examples could be playing a game, or a musical instrument. This state is characterized by a narrowing of the focus of awareness so that irrelevant perceptions are filtered out. People focus on the goals of the task that they are performing and they perceive a sense of control over the environment.

The experience of flow is associated with positive affect—people remember these situations as pleasurable. It may be participation as a violin player in an orchestra, solving math problems, or playing chess. All of these cases may involve a sense of total attention and accomplishment which the person thinks of as a pleasurable experience.

Flow has been studied in a broad range of contexts, including sports, work, shopping, games, hobbies, and computer use. It has been found useful by psychologists, who study life satisfaction, happiness, and intrinsic motivations; by sociologists, who see in as the opposite of anomie and alienation; by anthropologists, who are interested in the phenomenon of rituals.

Webster et al. (1993) suggested that flow is a useful construct for describing human-computer interactions. They claimed that flow has the effect when users perceive a sense of control over the interactions with technology. They also perceive that their attention is focused on the interaction. As a result their curiosity is aroused during the interaction, and they find the interaction interesting.

In e-commerce, a compelling design of a website should facilitate a state of flow for its customers.

Hoffman and Novak (1996) defined flow as a mental state that may occur during network navigation. It is characterized by a seamless sequence of responses facilitated by machine interactivity. It is enjoyable and there is a loss of self-consciousness. To experience flow while engaged in any activity, people must perceive a balance between their skills and the challenges of the interaction, and both their skills and challenges must be above a critical threshold.

Games promote flow and positive affect (Johnson and Wiles, 2003). The study of games can also provide information on the design of nonleisure software to achieve positive affect. Bergman (2000) noted that the pleasure of mastery can only occur by overcoming performance obstacles, so that the user can work without interruptions. He will then obtain a sense of accomplishment. Thus, an interface may be designed that can improve a user's attention and make the user feel in total control as well as free of distractions from nonrelated tasks, including poor usability.

### 3.5 Endowment Effect

Research on the *endowment effect* has shown that people tend to become attached to objects they are endowed with, even if they did not have any desire to own the object before they got possession of it (Thaler, 1980). Once a person comes to possess a good, he or she values it more than before possessing it. This psychology works well for companies that sell a product and offer a two-week return policy. Very few return the product. Put simply, this means that people place an extra value on the product once they own it.

Lerner et al. (2004) extended the endowment effect by examining the impact of negative emotions on the assessment of goods. As predicted by appraisal-tendency theory, disgust induced by a prior, irrelevant situation carried over to unrelated economic decisions, thereby reducing selling and choice prices and eliminating the endowment effect. Sadness also carried over, reducing selling prices but increasing choice prices. In other words, the feeling of sadness produces a *reverse endowment effect* in which choice prices exceeded selling prices. Their study demonstrates that incidental emotions can influence decisions even when real money is at stake and emotions of the same valence can have opposing effects on such decisions.

### 3.6 Hierarchy of Needs

According to Maslow (1968), people have hierarchies of needs that are ordered from physiological to safety, love/belonging, esteem, and self-actualization. They are usually depicted using a pyramid or a staircase, such as in Figure 6. The hierarchy affects how needs are prioritized. Once a person has fulfilled a need at a lower level, he or she can progress to the next level. To satisfy the need for self-actualization, a person would have to fulfill the lower four needs, which Maslow (1968) referred to as *deficiency needs*. These needs are different in nature to self-actualization. Many authors have pointed out that the hierarchy is not a strict progression. For example, some individuals may deemphasize safety but emphasize the needs for love/belonging.

Hancock et al. (2005) presented a hierarchy of needs for ergonomics and hedonomics (Figure 6). The ergonomic needs address safety, functionality, and usability; in Maslow's reasoning these would be referred to as deficiency needs. The two upper levels, pleasure and individuation, deal with self-actualization. Individuation, at the top of the pyramid, is concerned with ways in which a person customizes his or her engagement and priorities, thereby optimizing pleasure as well as efficiency.

One may question if there is really a hierarchy or if the elements of Figure 6 are independent of each other. If so, the progression would not be from bottom to top but rather in parallel. Helander and Zhang (1997) found that comfort and discomfort are orthogonal concepts, and it is necessary to use two different scales to measure them. Similarly, it may be necessary to use several scales in Figure 6 to measure each of the five concepts. Essentially, a combination of subjective and objective measures is needed to capture the various dimensions of emotion.

## 4 MEASUREMENT OF AFFECT EMOTION, AND PLEASURE

The measurement of affect in human factors research is complex and challenging. Although a number of methods for measuring affect have been developed, their applicability and effectiveness in different contexts remain questionable. Evaluation of affective design in product development is much more difficult than evaluation of technical (e.g., performance requirements) and business-related (e.g., market shares, sales) matters. Affect in design is sometimes fuzzy and may be better understood from an intuitive and personal viewpoint. As such, it is difficult to evaluate affective design from an objective and systematic approach (Khalid, 2008).

However, affective design has become increasingly important in industry. The impact on customer satisfaction, sales figures, and corporate core values demands greater treatment of the issues for integration into the product development processes. Moreover, affective design measures need to be derived and communicated explicitly to the designers. For this reason, there is a need to identify methods and tools that support a systematic approach to affective design.

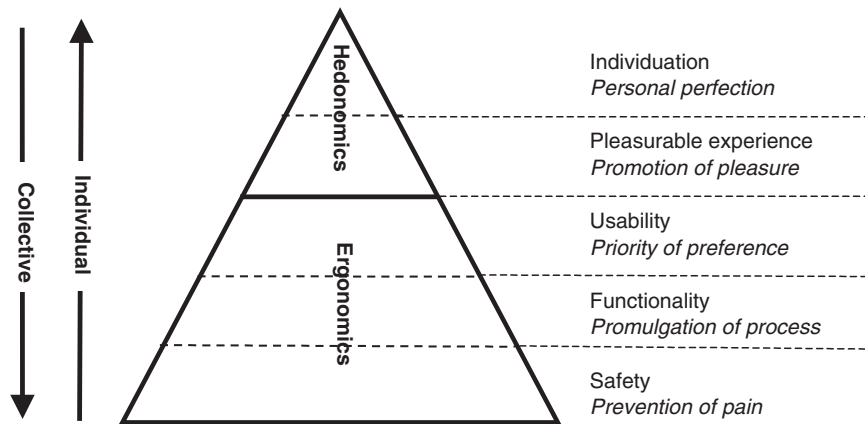
Several methods have been developed for measuring and analyzing affect in HCI (Shami et al., 2008; Ashkanasy and Cooper, 2008) and product design (Khalid et al., 2011; Xu et al., 2009; Hekkert and Schifferstein, 2008). However, these methods are sometimes difficult to be used directly in industry. First, knowledge on methods that are appropriate and useful for design of specific products in industry is still limited. Second, many methods are developed in academia and may not be directly adaptable to the constraints and requirements in industry. Third, most methods require knowledge of how to use them in order to be reliable and valid. Figure 7 provides an overview of the existing methods that have been employed in product design.


**Figure 6**   Hierarchy of ergonomics and hedonomic needs (Hancock et al., 2005).

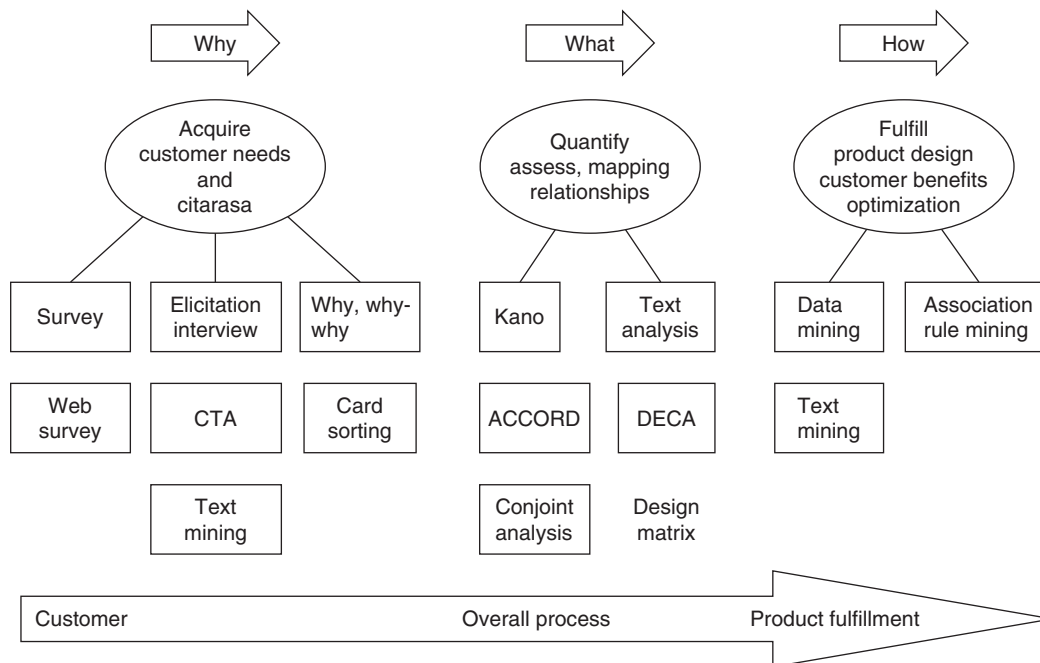

**Figure 7**   Overview of methods for affective engineering and design.

The why-why-why method has proven effective in eliciting customers' affect (Goh, 2008; Helander and Khalid, 2009; Khalid et al., 2011). The method was applied in the CATER project (Khalid et al., 2007a) to generate customers' needs and requirements as mentioned above.

### 4.1   Measurement Issues

To measure affect, emotions, or pleasure of users in relation to a product or system, we need to consider five

pertinent issues: dynamics, context, reliability, validity, and error (Larsen and Fredrickson, 1999).

### 4.1.1   Dynamics

Emotions are generated by different systems in the brain with different timing mechanisms, and they evolve over time. They are difficult to capture, which raises three critical issues that need to be addressed: (1) how to identify the onset and end of a particular emotion, (2) how to ensure that a measure of emotion can capture the duration, and (3) how to compare over

time the subjective emotion experience to the measured experience.

### 4.1.2 Context

Emotions occur in a context. Activity theory, for example, emphasizes the ongoing work activity. Therefore, it is important to capture the context and the peculiarities of the scenario in which the emotions were generated. Emotions also vary from person to person and are related to personality, experience, mood, and physiological arousal. In addition, the 24-h circadian rhythm influences the emotion experience.

### 4.1.3 Reliability

Finding measurements that are stable from time to time may prove problematic because a person's mood changes frequently and it may be difficult to reproduce the emotive experience a second time for a retest. For some situations, a test–retest correlation is a good estimate of reliability. Emotion can also be measured for members in a group. The interest here may be differences between people in their reactions to emotion-provoking events such as disasters (Khalid et al., 2010).

### 4.1.4 Validity

Determining whether a measure that we use to evaluate emotion(s) measures what we intend to measure is always a concern due to the fact that emotions are complex responses. As such, the measurement of an emotion cannot be reduced to one single measure (Larsen and Fredrickson, 1999).

Defining measure(s) linked to a theory can enhance construct validity. But it also simplifies measurement since the focus may be on only a few types of measures. For example, measuring the "pleasures of the mind" construct may be linked to a theory of emotional expression that restricts selection of dependent variables since these do not necessarily generate a facial expression or physiological response. Therefore, we would not consider either physiological variables or facial measures.

### 4.1.5 Measurement Error

There are two types of measurement error: random error and systematic error. To overcome random error, one can take many measures instead of a single measure and estimate a mean value. Therefore, multiple items or mathematical measurement models can be used to control or eliminate random measurement error. However, this approach is not suitable for methods which require assessments at certain times, such as experience sampling.

Another problem is that some types of assessments are intrusive (Schimmack, 2003). By asking a person to respond to a question, the contextual scenario of the emotional experience is disrupted, which may reduce the validity of the data. To minimize disruption, one can reduce the number of questions. Another way is to seek measures that are less intrusive, for example, physiological responses and facial expressions.

For heterogeneous scales that sample a broad range of affects (e.g., PANAS scales), many items are needed.

Watson et al. (1988) used 10 items and obtained item–factor correlations ranging from 0.75 to 0.52. Systematic measurement error does not pose a problem for within-subject analysis because the error is constant across repeated measurements. However, it can be misleading to use average values for calculation of correlation coefficients.

Below we present some methods that have been developed in human factors, product design and computing for the measurement of affect and emotions.

## 4.2 Methods in Affective Engineering

The methods for measuring affect or emotions are no longer entrenched in human factors alone. Research in consumer behavior, marketing, and advertising has developed instruments for measuring emotional responses to advertisement and consumer experiences of products. Since this is an area of great activity, we focus on methods that relate to affective design of products. The methods are classified into four broad categories: (1) subjective, (2) objective, (3) physiological, and (4) performance. The subjective methods are further categorized into three classes of measures: (1) user ratings of product characteristics, (2) user ratings of emotions and/or reporting of user experience without specific reference to an artifact, and (3) user ratings of emotions as induced by artifacts. Table 5 summarizes the methods.

### 4.2.1 Subjective Measures

***Ratings of Product Characteristics*** These subjective methods involve user evaluations of products. There are two established techniques: kansei engineering (Nagamachi, 2010; Nagamachi and Lokman, 2010) and semantic scales (Osgood et al., 1967). We introduce Citarasa engineering (Khalid et al., 2011) to complement these methods, and it is presented as a case at the end of this section.

***Kansei Engineering*** The method centers on the notion of *kansei* or customer's feelings for a product (Nagamachi, 2001, 2008; Khangura, 2009; Schutte et al., 2008). The word "kansei" encompasses various concepts, including sensitivity, sense, sensibility, feeling, aesthetics, emotion, affection, and intuition—all of which are conceived in Japanese as mental responses to external stimuli, often summarized as psychological feelings (Krippendorff, 2006).

Kansei engineering may be conceived as a five-stage process (Kato, 2006):

1.  *Perception Kansei*. The process of perceiving information received from objects or media via the human five senses at the physical, physiological, psychological, and cognitive levels. Different levels of appreciation may result in information being processed differently by each individual.

2.  *Situation Kansei*. The process of subjective interpretation of the situation in which the person is placed. Although people can be in the

**Table 5 Overview of Affective Engineering Methods**

same location at the same time, they can feel differently of the situation due to differences in lifestyles and behaviors of the day.

3. *Knowledge Kansei*. The process of organizing the knowledge base within one's own memory in terms of, for example, association rules. Differences may be due to an individual's personal interests, resulting in differences in vocabulary to express the experience and the associated organization.

4. *Action/Expressive Kansei*. The process of taking specific action or expressing information, in various media, to the external world through the physical body or an electronic gadget. Differences in behavior habits (rules) may account for skill differences and also for differences in action patterns.

5. *Intention Kansei*. The process of selecting action and expression (output) from sensory images and interpretations of a situation (input). This

process is based upon a person's internalized objective. Differences in lifestyles form the differences in response relationships between input and output. This process, which is akin to goal driven, links the above processes together.

Some aspects of the above processes are translated into the following basic procedure in kansei engineering (Nagamachi, 2001): (1) collect kansei words; (2) correlate design characteristics with kansei words (e.g., using Osgood's semantic differential technique); (3) perform factor analysis on kansei words to determine similarity; and (4) analyze product features to predict emotions.

The method has been expanded to use statistical visualization techniques (Ishihara et al., 2009), fuzzy logic (Lin et al., 2007), and data mining (Jiao et al., 2006). Besides automobiles (Bahn et al., 2009; Schutte and Eklund, 2005), other products that have applied the kansei method include mobile phones (Kuang and Jiang, 2009), footwear (Bouchard et al., 2009), home design (Nagamachi, 2008), and robotics (Saerbeck and Bartneck, 2010). Kansei engineering has also been applied to services (Hartono and Tan, 2009) and surface roughness (Choi and Jun, 2007).

In product platform development of mobile phones (Kuang and Jiang, 2009), the procedure involves (1) identifying platform and individual parameters, then quantifying the relationship between the product's perceptual image and the design parameters by using regression analysis from an affective evaluation survey; (2) grouping customers' responses according to their preference similarity coefficients by a cluster analysis of the preference evaluation survey in which the values of the platform parameters are fixed, then determining the number of platforms based on the clusters; (3) establishing the quantified relationship between the average preference and the individual parameters for each cluster using the regression method; and (4) determining the values of the individual parameters based on the satisfaction of each customer group. The product platform developed by the proposed method can achieve customer satisfaction, and a company can combine the simple individual form elements to the platform to rapidly develop a customized product form to meet a certain customer's affective need.

In short, the kansei engineering method has expanded extensively beyond the Japanese borders since it was first introduced in 1970s. A society by the same name is operating actively in Japan, with members across the globe. The Kansei Engineering Society also hosts conferences with the most recent in France called KEER 2010 (Kansei Engineering and Emotion Research).

**Semantic Scales** Semantic scales are similar to scales used in kansei engineering. The main difference is that the scales rely on the methodology proposed in Osgood's semantic differential (SD) technique (Osgood et al., 1967). This technique makes it possible to assess semantic differences between objects. Adjective pairs of opposite meanings are created, such as light–heavy, open–closed, and fun–boring. Subjects then rate objects using, for example, a five-point scale, such as 1 (very fun), 2 (fun), 3 (neutral), 4 (boring), and 5 (very boring). A main problem is to validate the word pairs. In the first place it is not trivial to assess if the two words constitute semantic opposites. One would also need to demonstrate that the chosen word pair is appropriate to evaluate the artifact in question. In our opinion it is easier to use scales that are unipolar; this is because it is difficult to find semantic opposites of words.

Chen et al. (2009) explored relationships between touch perception and surface physical properties using a semantic differential questionnaire to assess responses to touching the textures of confectionary packaging such as cardboards, laminate boards, and flexible material against six word pairs: warm–cold, slippery–sticky, smooth–rough, hard–soft, bumpy–flat, and wet–dry. In addition, they obtained four physical measurements to characterize the surfaces' roughness, compliance, friction, and rate of cooling of an artificial finger when touching the surface. Results of correlation and regression analyses showed that touch perception is associated with more than one physical property and the regression model can represent both strength and form.

Karlsson et al. (2003) used Küller's (1975) method that was developed for architectural appreciation in design; however, they applied to the automobile. They obtained significant results that discriminated between the designs of four passenger cars: BMW 318 (more complex and potent), Volvo S80 (more original and higher social status), Audi A6 (less enclosed), and VW Bora (greater affect). Considering the significant results, one may debate whether formal validation is necessary; the significant results carried much face validity. Obviously, this methodology works well with cars as well as architecture.

Chen et al. (2003) proposed a framework for understanding how product shapes evoke affective responses. For a set of representative product shapes, they first conduct a survey to evaluate the affective characteristics of each product shape. They then compute a spatial configuration that summarizes the affective responses toward the set of shapes by applying perceptual mapping techniques to the survey data. A series of new product shapes that smoothly interpolate among product shapes were then generated by using image-morphing techniques. With data from a follow-up survey, they inserted the new shapes into the spatial configuration. The trajectory or distribution of the interpolated shapes provided visualization of how affective characteristics changed in response to varying shapes. They found the relationship between the shapes and the affective characteristic to be nonlinear and nonuniform.

Wellings et al. (2010) applied the SD rating scale to measure the "feel" of push-switches in five luxury saloon cars both in context (in-car experience) and out of context (on a bench). Besides semantic scales they also obtained hedonic data on subjective liking. Factor analysis showed that perceived characteristics of switch haptics can be explained by three factors: *image, build quality*, and *clickiness*.

Khalid and Helander (2004) developed a rating tool to measure user responses to four future electronic

devices [cell phone, personal digital assistant, radio, and geographical positioning system (GPS)] for an instrument panel of a car. Users had to imagine the products and rated their affective preferences for 15 product attributes on 10-point SD scales. These attributes comprised functional and affective customer needs derived from a customer survey. Using factor analysis, three generic factors were extracted: *holistic attributes, styling*, and *functional design*. Depending upon the familiarity of the device there were clear differences among users. Devices that were unfamiliar to the test persons, such as GPS, were assessed using holistic attributes. Familiar designs, such as car radio and cell phone, were assessed using styling and functionality attributes.

More recently, Chuang and Chen (2008) introduced the hierarchical sorting method and divide-and-conquer method to improve the efficiency of rating a large number of visual stimuli, such as armchairs, derived from multiple attribute scales. The attribute data collected by both methods were quite consistent with an average correlation of 0.73. As such, the methods were proven to be more efficient than the manual card-sorting method. Depending on the objective of the perceptual task, the hierarchical sorting method is effective for distinguishing details in visual differences among similar stimuli relative to the divide-and-conquer method.

Alcantara et al. (2005) applied SD to structure the semantic space of casual shoes. Sixty-seven volunteers evaluated 36 shoe models on 74 adjectives that formed the "reduced semantic universe." Factorial analysis of principal components was used to identify the semantic axes. A statistical index was introduced to measure the subject's consensus and then used to analyze the influence of the number of volunteers in the semantic evaluation results. The results showed that comfort and quality were independently perceived by consumers; whereas comfort was clearly identified by users, quality was not.

### Subjective Ratings of Emotions

These include techniques that report a person's subjective experience, such as self-reports and experience sampling method, or rating of one's own emotions in the form of affect grid, checklist, and interview. These methods have more general applicability to products as well as tasks and scenarios.

### Self-Reports

This technique requires participants to document their subjective experiences of the current situation. A self-report can reflect on one's present state and compare it to the past state. As such, the self-reporting technique relies on the participant's ability to report experiences and to reflect accurately on their experiences. The measures may be instantaneous or retroactive. Instantaneous reports refer to the emotion as first experienced, while retrospective reports refer a situation after the fact. Such assessments can be complemented using a video as a reminder.

Self-report measures involve a plethora of affect inventories: verbal descriptions of an emotion or emotional state, rating scales, standardized checklists, questionnaires, semantic and graphical differentials, and projective methods. Criticisms of self-report methods include the possibility that they draw attention to what the experimenter is trying to measure, that they fail to measure mild emotions, and that they are construct valid (Isen and Erez, 2006).

Lottridge (2008) measured emotional responses based on the model of valence and arousal. Reactions to storyboard and video prototypes in a pilot study motivated the need for continuous affective self-reports. An experiment then compared the relative ease of use and the cognitive complexity of different methods of emotional measurement.

A major limitation of the self-report is that it relies exclusively on the person's cognitive labels of emotions to remember and summarize their experiences over longer or shorter intervals of time. But emotion, as argued above, is a multichannel phenomenon and is not limited to the cognition of emotion. In addition, there are physiological, facial, nonverbal, behavioral, and experiential elements (Diener, 1994). Self-reports of emotional well-being, such as happiness, tend to reveal greater consistency than many other types of emotion (Brown and Schwartz, 1980). There is also agreement between self-reports of emotional well-being and interview ratings, peer reports, and memory for pleasant events (Sandvik et al., 1993).

### Experience Sampling Method (ESM)

Coined by Larson and Csikszentmihalyi (1983), ESM measures people's self-reported experiences close in time to the occurrence of the scenario that evoked the emotion. Typically ESM uses a combination of online and short-term retrospective question formats in which people report what is presently or recently occurring (e.g., "How do you feel *right now*? How did you feel *this past hour*?"). As such, these procedures measure subjective experience that is episodic in nature.

ESM was designed to capture user experiences in the field. Initially ESM took advantage of the popularity of earlier mobile devices (e.g., pagers) to ask people for feedback at random times during the day. This configuration aimed to reduce problems that participants might have when recalling events, a problem underlying many self-report techniques (Hektner et al., 2007). With ESM, participants make a quick record close to the moment of interest, rather than having to recall what they did in the past.

As mobile technology evolves, the sampling process becomes more intelligent and sensitive to the context of the product use (Lew, 2009). Nowadays, researchers can use selective sampling (Consolvo et al., 2007), a sampling technique that links the timing and questions to relevant events using a portable device that collects user feedback. The device's ESM controller uses sensor data that could capture contextual as well as user product events to select relevant sampling moments. In addition, the controller, based on the same information, may decide what question or flow of questions should be asked and how they should be presented together with the format of the answers.

A common challenge when using ESM is to maximize the quality and quantity of the samples while

minimizing interruptions and maintaining the motivation of the participants. The development of strategies to optimize sampling, interruptions, and motivation has been the key focus in recent ESM research (Kapoor and Horvitz, 2008). Using these strategies, timing and content of questions can be adapted to the actual state and context of the participants and the product.

Experience sampling techniques can be used to study user experiences with products in a natural setting and over time (Vastenburg and Hererra, 2010). Currently, researchers can use selective sampling to link the timing and questions to relevant product events and contextual events. Existing research has focused on maximizing the quality and quantity of feedback, while at the same time minimizing interruptions and maintaining the motivation of the participants. Adaptive experience sampling is a method that enables researchers and designers to change the focus of their experience sampling study on the fly.

**Affect Grid** Developed by Russell et al. (1989) the technique measures single-item affect in the form of a square grid anchored horizontally with pleasure/displeasure (valence) and vertically with arousal/sleepiness (activation). On the basis of subjective feelings, a subject places an X along two dimensions: pleasantness and arousal. Both aspects will be rated; if both are rated highly, the subject feels great excitement. Similarly, there are feelings of depression, stress, and relaxation. The affect grid displays strong evidence of discriminant validity between the dimensions of pleasure and arousal. Studies that used the affect grid to assess mood provided further evidence of construct validity. However, the scale is not an all-purpose scale and is slightly less reliable than a multiple-item questionnaire for self-reported mood.

Studies that measured more subtle affective states than the main dimensions of valence, arousal, and dominance have had some but more limited success—for example, mapping subtle affective attributes to a defined subregion of a two-dimensional (2D) valence and arousal grid (Killgore, 1998). Similarly, Warr (1999) used the same scale to measure well-being along a 2D framework of well-being in terms of the location in this 2D space of arousal and pleasure. A particular degree of pleasure or displeasure may be accompanied by high levels of mental arousal or a low level of arousal (sleepiness), and a particular level of mental arousal may be either pleasurable (pleasant) or unpleasurable (unpleasant) (Warr, 1999).

**Checklists.** Mood checklists comprise lists of adjectives that describe emotional states. Subjects are required to check their emotions. The mood adjective checklist (MACL) developed by Nowlis and Green (1957) contains 130 adjectives with a four-point scale: "definitely like it," "slightly," "cannot decide," and "definitely not."

Hodgetts and Jones (2007) used a mood checklist as an interrupting task in an on-going performance of Tower of London (ToL) problems. A list of six statements along a mood continuum (e.g., "extremely happy" to "extremely sad") was presented in the center of the screen and participants were asked to select the one that best applied to them. This task was irrelevant to the main ToL problem. The number of mood checklists to be presented was manipulated—in three, five, or seven—but the precise timing of these was controlled by the participant rather than the computer program. The mood checklist interruptions were brief and undemanding in content, comparable to many types of pop-ups that increasingly invade our computer screens. Despite its brief duration, the interruption affected task performance.

Zuckerman and Lubin (1965) developed the multiple-affect adjective checklist (MAACL) comprising 132 items, which they revised in 1985 (MAACL-R). The revised version allowed scoring of several pleasant emotions, taking into account global positive and negative affect as well as sensation seeking. The revised MAACL-R scale is an alternative to the profile of mood states (POMS) scale (McNair et al., 1971). The POMS is an assessment of transient mood states, measuring six factors: tension–anxiety, depression–dejection, anger–hostility, vigor–activity, fatigue–inertia, and confusion–bewilderment. Of the six factors, only one represents positive expressions (vigor–activity). Izard (1992) developed the multi-item differential emotional scale (DES) with the purpose of assessing multiple discrete emotions.

More recently, King and Meiselman (2009) developed EsSense Profile™ using the adjectives from POMS and MAACL-R scales. Terms were validated based on the clarity and usage frequency to ensure the application to a range of products. The final scale consisted of 39 emotions to represent consumer affective responses toward food.

**Interviews.** Interviews may be used to assess product pleasure and pleasure from activities or tasks. It is a versatile method and can be performed face to face or through phone conversation. Questions can be structured or unstructured (Jordan, 2000). A structured interview has a predetermined set of questions, whereas an unstructured interview uses a series of open-ended questions.

Housen (1992) proposed a nondirective, stream-of-consciousness interview. Participants are asked simply to talk about anything that comes to their mind as they look at a work of art. It is called the "aesthetic development interview." There are no directed questions that can influence the viewer's statement. It provides a window into a person's thinking and minimizes researcher biases or assumptions. To insure reliability and consistency in the evaluation, the interviews are often examined by two independent coders, and the coding is then charted graphically by computer to enable a comprehensive representation of all thoughts that went through the subject's head.

A combination of in-depth interviews and experience sampling was used to capture the causes and emotions experienced when interacting with products (Demir et al., 2009). The appraisal patterns elicited emotions of product users for four emotion groups: happiness/joy, satisfaction/contentment, anger/irritation, and disappointment/dissatisfaction.

**Subjective Ratings of Emotions Induced by Artifacts** These rating scales have been used to document how artifacts make a person feel. By asking a question such as "What does the look of this car make you feel?" the user is expected to evaluate his or her emotions in relation to the artifact.

**PANAS Scales** Watson et al. (1988) developed the positive affect–negative affect schedule (PANAS). The purpose of PANAS is to measure positive and negative mood states of a person during different times or contexts: the current day, a week, or a year. PANAS evaluates mood adjectives using a five-point scale: "not at all," "slight," "a little," "moderately," "quite a bit," and "very much." *Positive affect* (PA) refers to feelings of enthusiasm, alertness, and activeness. A high PA score reflects a state of "high energy, full concentration and pleasurable engagement" (Watson et al., 1988). *Negative affect* (NA), on the other hand, refers to feelings of distress and unpleasurable engagement.

To describe PA, 10 descriptors were used: attentive, interested, alert, excited, enthusiastic, inspired, proud, determined, strong, and active. NA is measured using the following 10 descriptors: distressed, upset, hostile, irritable, scared, afraid, ashamed, guilty, nervous, and jittery. The 10-item scales have been shown to be highly internally consistent, largely uncorrelated, and stable at appropriate levels over a period of two months. When used with short-term instructions (e.g., *right now* or *today*) they are sensitive to fluctuations in mood, but when longer term instructions are used (e.g., *past year* or *general*) the responses are stable.

Turner et al. (2008) used the PANAS schedule to explore the relationships between comfort in making and receiving mobile phone calls in different social contexts, their affective responses to public mobile phone use by others, and how such factors relate to personal attributes and specific beliefs about calling behavior. The results of factor analyses revealed "context" as the most important in mobile phone use, and users differed in the extent to which they felt comfortable making and receiving calls in different locations.

To investigate the relation between a robot motion and the perceived affective state of the robot, Saerbeck and Bartneck (2010) applied two scales: PANAS and SAM (self-assessment mannikins). They used two motion characteristics for the perceived affective state: acceleration and curvature.

**Questionnaire.** Philips Corporate Design developed a questionnaire for measuring pleasure from products (Jordan, 2000). The questionnaire has 14 questions, focusing on several feelings that a user may have: stimulated, entertained, attached, sense of freedom, excited, satisfaction, rely, miss, confidence, proud, enjoy, relax, enthusiastic, and looking after the product. Using a five-point scale, ranging from disagree (0) to neutral (2) and strongly agree (4), the questionnaire covered most of a user's possible responses. To measure pleasure, open-ended items were added as an option. This was particularly useful to inform the product developers about the users' evaluation of pleasure.

Khalid et al. (2007b) developed two questionnaires to elicit citarasa in vehicle customers. The CARE (car evaluation) questionnaire was created for car customers and the TNT (truck needs tracker) questionnaire for truck customers. The CARE tool is an open-ended questionnaire with 60 questions which required detailed responses from the participant. In addition, there were close-ended questions for customer personal data and knowledge. The questions were driven by the *citarasa* model (see Figure 5). There were four parts:

*Part I: Customer Experience and General Needs.* Elicited customer experiences with the car, such as driving experience, previous experience, and expected criteria. The information was needed for the "marketing" section in the model, which focused on factors such as price, and customer information. Questions were designed to probe customers about cars driven currently and previously and whether it constituted a good buy. To measure customer citarasa relating to visceral, behavioral, and reflective design, questions addressed sensory characteristics (tactile, visual, olfactory, and auditory), functional requirements, and needs for trends, status, and style.

*Part II: Specific Requirements for Design.* Measured affective and functional requirements of existing cars and images of cars. The purpose was to generate a set of citarasa descriptors for developing the citarasa engineering database. Questions addressed both exterior and interior requirements of cars, and they were partially based on samples drawn from the Consumer Reports (2007) Annual Car Reliability Survey.

*Part III: Customer Expertise.* Evaluated customer knowledge, expertise, goals, and affordance. This relates to the "design goals, constraints" and "marketing" aspects of the citarasa model. Questions include how to obtain information on cars and how to decide it is a good car.

*Part IV: Customer Demographics.* Recorded driving experience, handedness, living arrangement, education level, and income. The data collected in this part were used to construct the "society" constraints in the model.

A pilot study was conducted to test the usability of the questionnaire. Questions that were found to be difficult or ambiguous were modified. The results were also used for creating response categories.

**Emotion Rating Scales** Several studies have developed methods and tools for measuring emotions in products. Desmet and Schifferstein (2008) proposed a method to measure complex emotions to product design using a nonverbal, cross-cultural tool called PrEmo® (Product Emotion Measurement Tool). PrEmo® consists of 14 animated characters expressing seven positive and seven negative emotions.

*Citarasa engineering* was developed in the CATER project. The method is driven by the concept of *citarasa* or *emotional intent* (Khalid et al., 2007a, 2011). Citarasa differs from kansei engineering as it has a theoretically

driven basis for elicitation and analysis of affective needs for vehicle design. The method has five steps as summarized in Figure 8.

A model of emotional intent was conceptualized. A semantic framework of citarasa words was then developed to map words to specific vehicle components to form citarasa ontology. Customer citarasa were then elicited in the field using probe interview technique. Affective needs were refined through Web surveys; finally the elicited citarasa were analyzed using data-mining techniques and the citarasa analysis tool. The tool is linked to the citarasa database, which enables analysis of affective needs in several countries in Europe and Asia. The system has been technically verified, validated, and tested for usability with consumers and automotive end users.

Unlike other methods that relied solely on subjective rating, this methodology uses a multimethod approach to elicit affective descriptors—from interview to questionnaire, rating scale, ranking, and mood board. It was used to validate the descriptors in a Web-based tool called the Citarasa System (Khalid et al., 2009). The results were analyzed with WEKA, a data-mining method, and other statistical analyses, including correlation analysis, cluster analysis, and factor analysis.

### 4.2.2 Objective Measures

Two objective methods to record emotions are analysis of facial expressions and vocal content of speech or voice expressions.

*Facial Expressions* Numerous methods exist for measuring facial expressions (Ekman, 1982). Facial expressions provide information about (1) *affective state*, including emotions such as fear, anger, enjoyment, surprise, sadness, disgust, and more enduring moods such as euphoria, dysphoria, or irritableness; (2) *cognitive state*, such as perplexity, concentration, or boredom; and (3) *temperament and personality*, including such traits as hostility, sociability, or shyness.

Ekman and Friesen (1976) identified five types of messages conveyed by rapid facial signals: (1) *emotions*, including happiness, sadness, anger, disgust, surprise, and fear; (2) *emblems*, culture-specific symbolic communicators such as the wink; (3) *manipulators*, self-manipulative associated movements such as lip biting; (4) *illustrators*, actions accompanying and highlighting speech such as a raised brow; and (5) *regulators*, non-verbal conversational mediators such as nods or smiles.

Measurement of facial expressions may be accomplished by using the facial action coding system (FACS). The method, proposed by Ekman and Friesen (1976), captures the facial changes that accompany an emotional response to an event. FACS was developed by determining how the contraction of various facial muscles (singly and in combination with other muscles) changes the appearance of the face. Videotapes of more than 5000 different combinations of muscular actions were examined to determine the specific changes in appearance and how to best differentiate one appearance from another.

Measurement with FACS is done in terms of action units (AUs) rather than muscular units for two reasons. First, for a few changes in appearance, more than one muscle is used to produce a single AU. Second, FACS distinguishes between two AUs for the activity of the frontalis muscle that produces wrinkles on the forehead. This is because the inner and outer portion of

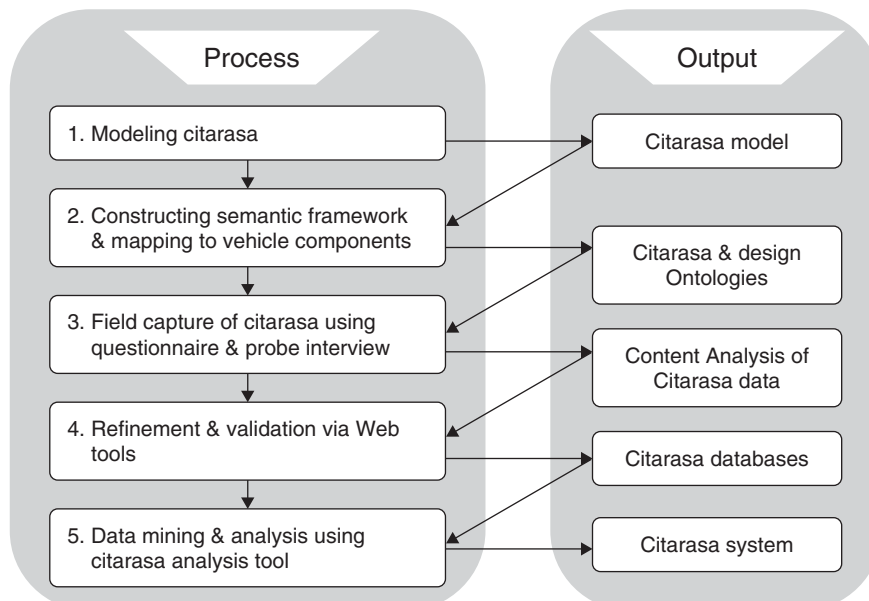

**Figure 8** Methodology for citarasa elicitation and analysis (Khalid et al., 2011).

this muscle can act independently, producing different changes in appearance. There are 46 AUs which account for changes in facial expression and 12 AUs which describe gross changes in gaze direction and head orientation. To use FACS the investigator must learn about the appearance and the muscles of the face for each AU. This demands much time and effort.

The maximally discriminative affect coding system (MAX) developed by Izard (1979) measures visible appearance changes in the face. The MAX units are formulated in terms of facial expressions that are relevant to eight specific emotions, rather than in terms of individual muscles. Unlike FACS, MAX does not measure all facial actions but scores only facial movements that relate to the eight emotions.

Facial changes can also be registered using electromyography (EMG). EMG measures nerve impulses to muscles which produce facial changes or expressions. This measure assumes that emotions are visible through facial expressions, which is the case when people interact with each other.

Davis et al. (1995) compared facial electromyography with standard self-report of affect. He obtained a good correlation between activity of facial muscles and self-report of affect. The pattern of muscular activation could be used to indicate categories of affect, such as happy and sad, and the amplitude of electromyographic signals gave information on degree of emotions. In other words, Davis et al. (1995) was able to categorize as well as quantify affective states using facial electromyography.

**Vocal Measures of Emotion**    Most of the emotions conveyed in speech are from the verbal content. Additionally, the style of the voice, such as pitch, loudness, tone, and timing, can convey information about the speaker's emotional state. This is to be expected because vocalization is "a bodily process sensitive to emotion-related changes" (Larsen and Fredrickson, 1999). A simple and maybe also the best way to analyze the emotional content would be to listen to recordings of voice messages. Scherer (1986) noted that judges seem to be rather accurate in decoding emotional meaning from vocal cues. Some emotions are easier to recognize than others. Sadness and anger are easiest to recognize, whereas joy, disgust, and contempt are difficult to recognize and distinguish from one another.

Maffiolo and Chateau (2003) investigated the emotional quality of speech messages used by France Telecom Orange. Each year, vocal servers were used to respond to hundreds of millions of phone calls. The audio messages can be help messages, navigation messages, and information messages. The purpose of the study was to create a set of voice messages that were perceived as friendly, sincere, and helpful. Later, Maffiolo et al. (2007) improved the automatic detection and characterization of emotion-related expressions in human voice by an approach based on human auditory perception. A listening test was set up with 72 listeners. The corpus was constituted of 18 voice messages extracted from a real-life application. Message segments of different temporal length were listened to by listeners who were asked to verbalize their perception. Fourteen metacategories were obtained related to age, gender, regional accent, timbre, personality, emotion, sound quality, expression style, and so on. The temporal windows of listening necessary for listeners to perceive and verbalize these categories underlie the building of submodels relevant to the automatic recognition of emotion-related expressions.

A more high-tech method is to digitize voice recordings and analyze the voice by decomposing the speech sound waves into a set of acoustic parameters and then analyze the psychoacoustics and psychophonetics content (Larsen and Fredrickson, 1999). This includes analysis of pitch, small deviations in pitch, speaking rate, use of pauses, and intensity.

*Emotive Alert*, a voicemail system designed by Inanoglu and Caneel of the Media Lab at the Massachusetts Institute of Technology (Biever, 2005), labels messages according to the caller's tone of voice. It can be installed in a telephone exchange or in an intelligent answering machine. It will analyze incoming messages and send the recipient a text message along with an emoticon indicating whether the message is urgent, happy, excited, or formal. In tests on real-life messages, the software was able to tell the difference between excited and calm and between happy and sad but found it harder to distinguish between formal and informal and urgent and nonurgent. This is because excitement and happiness are often conveyed through speech rate and volume, which are easy to measure, while formality and urgency are normally expressed through the choice of words and not easy to measure (Biever, 2005). At the present time the first method, listening to speech, is probably the more reliable.

Regardless of the method used, vocal measures of emotion are sometimes difficult to use since (1) voice is not a continuous variable as people do not speak continuously and thus vocal indicators of emotion are not always present; (2) positive and negative emotions are sometimes difficult to distinguish; and (3) the voice can reflect both emotional/physiological and sociocultural habits, which are difficult to distinguish (Scherer, 1998).

### 4.2.3  Psychophysiological Measures

Emotions often affect the activity of the autonomic nervous system (ANS) and thereby the activation level and arousal. At the same time, there are increases and decreases in bodily functions, such as in heart functions, electrodermal activity, and respiratory activity (Picard, 1997). Thus, there is a variety of physiological responses that can be measured, including blood pressure, skin conductivity, pupil size, brain waves, and heart rate frequency and variability. For example, in situations of surprise and startle, the electrical conductivity of certain sweat glands is momentarily increased. This is referred to as a galvanic skin response (GSR). These sweat glands are primarily found on the inside of the hands and on the soles of the feet. Electrodes are then attached to measure the electrical conductivity (Helander, 1978). The nerve signals take about 1.5 s to travel from the

brain to the hand, and therefore the response is a bit delayed.

Researchers in the field of affective computing are actively developing "ANS instruments," such as IBM's emotion mouse (Ark et al., 1999) and a variety of wearable sensors (e.g., Picard, 2000). With these instruments, computers can gather a multitude of psychophysiological information while a person is experiencing an emotion and learn which pattern is most indicative of which emotion.

ANS responses can be investigated in experiments, for example, by using film clips to induce the type of emotions investigated (e.g., amusement, anger, contentment, disgust, fear, sadness), while electrodermal activity, blood pressure, and an electrocardiogram (ECG) are recorded. Therefore, it is possible to associate a variety of emotions with specific physiological reactions.

While autonomic measures are fruitful, it is important to note that:

1. Autonomic measures vary widely in how invasive they are. The less invasive measures include pulse rate and skin conductance, while measures of blood pressure are often invasive since they use pressure cuffs which are deflated. This may distract a person, so that the emotion is lost.

2. The temporal resolution of various autonomic measures varies widely. Some measures are instantaneous, such as GSR, while impedance cardiography, for example, requires longer duration for reliable measurement (Larsen and Fredrickson, 1999).

3. Different measures have different sensitivity. Depending upon the emotion which is recorded, it is best to first validate the particular physiological measures so as to understand if it is sensitive enough to record differences in the intensity of the emotion.

Infrared thermography (IRT) offers human factors researchers a highly accurate, noncontact and objective measurement tool for exploring the dynamics of a user's affective state during user–product interaction. It provides useful visual and statistical data for designers to understand the nature and quality of user experience. Jenkins et al. (2009) compared thermographic, EEG, and subjective measures of affective appearance during simulated product interactions. The results showed the utility of IRT in the measurement of cognitive work and affective state changes but the causal relationships between facial temperature dynamics, cognitive demand, and affective experiences need to be explored further.

### 4.2.4 Performance Measures

These measures typically indicate the effect of emotions on decision making. Emotion-sensitive performance measures may be obtained through judgment tasks. One popular task is to have participants make probability estimates of the likelihood of various good and bad events. It has been shown that persons in unpleasant emotional states tend to overestimate the probability of bad events (Johnson and Tversky, 1983).

Ketelaar (1989) showed that people in a good mood also overestimated the probability of pleasant events. Another useful performance task is to ask participants to generate associations to positive, neutral, and negative stimuli. Mayer and Bremer (1985) showed that performance on this task correlated with the naturally occurring mood.

A second category of performance measures involves information-processing parameters. Reaction times in lexical decision tasks have been shown to be sensitive to affective states (Challis and Krane, 1988). The task involves judging if a string of letters presented on the computer screen represents a word or nonword. Participants in positive affective states are quicker and sometimes more accurate at judging positive words as words compared to participants in neutral states, and vice versa for unpleasant moods (Niedenthal and Setterlund, 1994).

## 5 CONCLUSION

The expectations of users in terms of customer needs are changing: Functionality, attractiveness, ease of use, affordability, and safety are taken for granted. The new trends are for objects or artifacts that inspire users, enhance their lives, and evoke emotions and dreams in their minds. In product design, there are two evaluations— the first one based on cognition (knowledge and functionality) and the second one on affect.

Professionals in human factors and HCI have come to realize that usability is not enough. The main goal is to please the user rather than maximize transactions and productivity. This is particularly critical for e-commerce and other Web-based activities, where there are many alternatives. Human–computer interaction may hence be designed to induce affective and memorable experiences.

There is no such thing as a neutral interface; any design will elicit emotions from the user and the designer. The designer should aim to enhance the user experience through a deliberate design effort, thus bridging the gap between the affective user and the designer's environment, as outlined in Figure 5 of the affective user-designer model. The user, on the other hand, will gain pleasurable experience from a more fun interface. This will promote productivity and enjoyment.

Affective engineering, which is concerned with measuring people's affective responses to products and identifying the properties of the products to which they are responding, is now expanding as a method for use in both research and the industry. The most commonly used approach is the self-report whereby adjectives that people use to describe the product are identified and embodied into a semantic differential scale or questionnaire with rating scale. The use of such subjective methods has drawbacks. They rely heavily on the use of words and adjectives. The subject's vocabulary should be taken into account, because some people may have little comprehension of some of the words used in the methods mentioned above. The subject should be allowed to use his or her principal

language, or else some feelings might be misinterpreted. The words or adjectives must be concise and easy to understand and take into account cultural as well as contextual factors (Larsen and Fredrickson, 1999).

Physiological methods (or nonverbal instruments) have a better advantage as they are language independent and can be used in different cultures. A second advantage is that they are unobtrusive and do not disturb participants during the measurement. There are however limitations to the physiological measures. They can only reliably assess a limited set of "basic" emotions and cannot assess mixed emotions. For pleasures of the mind, it is doubtful if any of the psychophysiological methods will be sensitive enough to capture the subtleness of emotions.

Objective methods such as vocal content and facial expressions can be used to measure mixed emotions, but they are difficult to apply between cultures. It would be important to make cultural comparisons between vocal and facial expressions. For this purpose a multimedia database can be developed and shared by the research community. The database could contain images of faces (still and motion), vocalizations and speech, psychophysiological correlates of specific facial actions, and interpretations of facial scores in terms of emotional state, cognitive process, and other internal processes. This would facilitate an integration of research efforts by highlighting contradictions and consistencies and suggesting fruitful avenues for new research.

# EQUIPMENT, WORKPLACE, AND ENVIRONMENTAL DESIGN

# CHAPTER 21

# WORKPLACE DESIGN

**Nicolas Marmaras and Dimitris Nathanael**
**National Technical University of Athens**
**Athens, Greece**

## 1 INTRODUCTION

Workplace design deals with the shape, the dimensions, and the layout (i.e., the placement and orientation) of the different material elements that surround one or more working persons. Examples of such elements are the seat, working surfaces, desk, equipment, tools, controls, and displays used during the work as well as the passages, windows, and heating/cooling equipment.

The ergonomic workplace design aims at improving work performance (both in quantity and quality) as well as ensuring occupational safety and health through:

- Minimizing the physical workload and the associated strain on the working person
- Facilitating task execution, that is, ensuring effortless information exchange with the environment, minimization of the physical constraints, and so on
- Achieving ease of use of the various workplace elements

Putting together a workplace which meets ergonomics requirements while at the same time satisfies task demands is not a trivial problem. In fact, to achieve this one should consider an important number of interacting and variable elements, and try to meet many requirements, some of which may be contradictory. As shown in Figure 1, in any work setting there is a continuous mutual adjustment between the workplace components, the task demands, and the working person.

This mutual adjustment is also subject to broader environmental conditions. Therefore, regardless of how well each individual component of the workplace is designed, the habitual body movement and postures in everyday work emerge by an exploration of the constraints and affordances of the workplace as a whole.

Consider, for example, a person working in a computerized office (task demand: work with a computer). If the desk (workplace component 1) is too low and the seat (workplace component 2) is too high for the anthropometric characteristics of the worker (characteristic of the working person), the worker will lean forward (awkward posture), with negative effects on his or her physical workload, health (particularly if he or she should work for a long period in this workplace), and finally overall performance. Furthermore, if behind the worker there is a window causing glare on the computer's screen (characteristic of the environment), he or she will probably bend sideways (awkward posture) in order to be able to see what is presented on the screen (task demand), causing similar effects. Consequently, when designing a workplace, one has to adopt a systemic view, considering at least the characteristics of the working person, the task demands, and the environment in which the task will be performed.

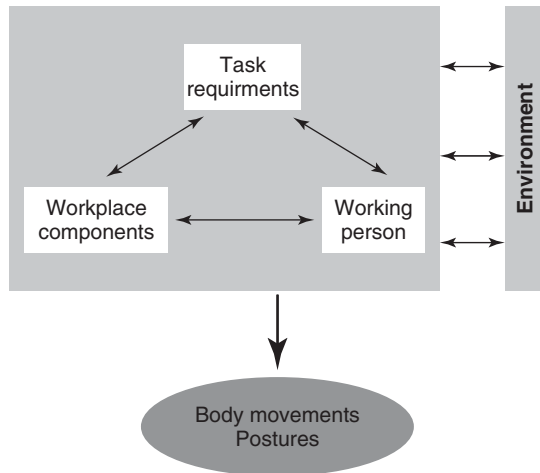
Furthermore, the elements of the work system are variable. The task demands may be multiple and variable. For example, at a secretarial workstation, the task may require exclusive use of the computer for a period of time, then data entry from paper forms, and then face-to-face contact with visitors. At the same time, the secretary should be able to monitor both the


**Figure 1** There is interdependence between the working person, task demands, workplace elements, environment, and body movements and postures.

entry and the director's doors. Finally, the workplace environment may be noisy or quiet, warm or cool, with annoying air streams, illuminated by natural or artificial light, and all the above may change during the course of a working day.

If to the complexity of the work system and the multiplicity of ergonomics criteria one adds the financial and aesthetic issues, successful design of a workplace becomes extremely complex. Hence, some people maintain that designing a good workplace is more an "art" than a "discipline" as there is no standard theory or method that ensures a successful result, the output depending heavily on the designer's "inspiration". Although this is true to a certain extent, good knowledge of the characteristics of the working persons who will occupy the workplace, of the tasks' demands, and of the broader environment, combined with an effort for discipline during the design process, contribute decisively to a successful design.

### 1.1 Importance of Satisfying Task Demands

Despite the multiple external determinants, the workplace still leaves many degrees of freedom to the working person, who can exploit them in more than one ways. As stated above, the habitual body movement and

postures in everyday work emerge by an exploration of the constraints and affordances of the workplace. This exploration and adaptation process can be considered as a control task: The working person, exploring the constraints and affordances of the workplace, tries to achieve an optimal balance between multiple demands related to the task, his or her physical abilities, and perceived comfort.

This control task can be approximated by a cybernetic model such as the one depicted in Figure 2 (Marmaras et al., 2008). According to this model, the postures adopted by the working persons are under the influence of two nested feedback loops: (a) a positive-feedback loop regarding the satisfaction of task demands (e.g., easy reading and writing for an office worker) and (b) a negative-feedback loop regarding the attenuation of the perceived physical strain and pain due to the body postures and the eventual disorders built because of them. These two loops work toward different objectives (i.e., meeting task demands vs. comfort satisfaction). The simultaneous satisfaction of both objectives may be conflicting. In such situations their resolution involves a trade-off which will be moderated by the feedback power and the pace of incoming information for each of the two loops. However, the two loops operate on different time scales. The positive one regarding the satisfaction of task demands is immediate and constantly perceived, easily linked to the particular arrangement of the various workplace components, and equally easily interpretable (e.g., if an office worker cannot access the keyboard because it is probably placed too far, he or she will move either the keyboard or the chair or extend his or her upper limbs). The negative loop, regarding the attenuation of the perceived physical strain and pain, takes time to be perceived as it has a cumulative character, requiring prolonged exposure (e.g., it takes months or years for musculoskeletal disorders to be built). Furthermore, such feedback is not easily interpretable and attributable to either postures or workplace settings by a nonexpert (e.g., even if back pain is felt, it is difficult for an individual to attribute it to a specific posture or workplace setting).

We can argue therefore, that workers' postures are more readily affected by the positive-feedback loop, which as a constant attractor forces the system to be self-organized in a way that favors the satisfaction of task demands. Such an argument has already been validated by Dainoff (1994) in a research conducted in laboratory settings. This research indicated that

**Figure 2** Cybernetic model depicting working person's control task related to body posture modifications.

participants performing a high-speed data entry task found it effective to sit in the forward-tilt posture, while participants who performed screen-based editing tasks (with very low keying requirements) found the backward-leaning posture more effective.

The model presented above stresses both the existence of regulation mechanisms operating continuously as part of the working person's activities and the need to put the task demands and resulting work activities at the center of the design process. It is the latter that makes the ergonomic design synonymous to the user-centered design.

The present chapter is mainly methodological; it presents and discusses a number of methods, techniques, guidelines, and typical design solutions which aim to support the decisions to be taken during the workplace design process. The next section discusses the problem of working postures and stresses the fact that there is no *one best posture* which can be assumed for long periods of time. Consequently, the effort should be put on designing the components of the workplace in such a way as to form a "malleable envelope" that permits the working persons to adopt various healthy postures. The two remaining sections deal with the design of individual workstations and with the layout of groups of workstations in a given space.

## 2   PROBLEM OF WORKING POSTURES

A central issue of the ergonomic workplace design is the postures the working person will adopt. In fact, the decisions made during the workplace design will affect to a great extent the postures that the working person will be able to adopt or not. The two most common working postures are sitting and standing. Between the two, the sitting posture is of course more comfortable. However, there is research evidence that sitting adopted for prolonged periods of time results in discomfort, aches, or even irreversible injuries. For example, Figure 3 shows the most common musculoskeletal disorders encountered at office workstations.

Studying the effects of "postural fixity" while sitting, Griego (1986) found that it causes, among others, (i) reduction of nutritional exchanges at the spine disks and in the long term may promote their degeneration, (ii) static loading of the back and shoulder muscles, which can result in aches and cramping, and (iii) restriction in blood flow to the legs, which can cause swelling (edema) and discomfort. Consequently, the following conclusion can be drawn: The workplace should permit the alteration between various postures because there is no "ideal" posture which can be adopted for a long period of time.

Based on this conclusion, the standing–sitting workstation has been proposed, especially for cases where the task requires long periods of continuous work (e.g., bank tellers or assembly workstations). This workstation permits to perform a job alternating the standing with the sitting posture (see Figure 4 for an example).

Despite the absence of an ideal posture, there are however postures which are more comfortable and healthy than others. The ergonomic research aims at identifying these postures and formulating requirements and principles which should be considered during the design of the components of a workplace. In this way the resulting design will promote healthy work postures and constrain the prolonged adoption of unhealthy postures.

**Figure 4**   Example of standing–sitting workstation.

**Figure 3**   Common musculoskeletal disorders encountered at office workstations.

## 2.1  Sitting Posture and Seats

The problem of designing seats that are appropriate for work is far from solved. In recent decades the sitting posture and the design of seats have attracted the interest of researchers, designers, and manufacturers due to the ever-increasing number of office workers and the importance of musculoskeletal problems encountered by them. This has resulted in the emergence of a proper research domain and subsequently to a plethora of publications and design solutions (see, e.g., Lueder and Noro, 1994; Mandal, 1985; Marras, 2005; Corlett, 2009).

As already stated, sitting posture poses a number of problems at a musculoskeletal level. One of the more important of them is *lumbar kyphosis*. When one is sitting, the lumbar region of the back flattens out and may even assume an outward bend. This shape of the spine is called *kyphotic* and is somewhat the opposite to the *lordotic* shape of the spine when someone is standing erect (Figure 5). The more the angle between the thighs and the body is smaller, the greater the kyphosis. This occurs because of the restrained rotation of the hip joint, which forces the pelvis to rotate backward. Kyphosis provokes increased pressure on the spine disks at the lumbar portion. Nachemson and Elfstrom (1970), for example, found that unsupported sitting in upright posture resulted in a 40% increase in the disks' pressure compared to the pressure when standing. There are three complementary ways to minimize lumbar kyphosis: (i) by using a thick lumbar support; (ii) by reclining the backrest; and (iii) by providing a forward-tilting seat. Andersson et al. (1979) found that the use of a 4-cm-thick lumbar support combined with a backrest recline of 110° resulted in a lumbar curve resembling closely the lumbar curve of a standing person. Another finding of Andersson et al. (1979) was that the exact location of the support within the lumbar region did not significantly influence any of the angles measured in the lumbar region. The studies
of Bendix (1986) and Bridger (1988) support the proposition of Mandal (1985) for the forward-tilting seat.

Considering the above, the following ergonomics requirements should be met:

1. The seats should dispose a backrest which can recline.
2. The backrest should provide a lumbar support.
3. The seat should provide a forward-tilting seat.

However, as Dainoff (1994) observes, when tasks require close attention to the objects on the working surface or the computer screen, people usually bend forward, and the backrest support becomes useless.

A design solution which aims to minimize lumbar kyphosis is the *kneeling* or *balance chair* (Figure 6), where the seat is inclined more than 20° from the horizontal plane. Besides the somewhat unusual way of sitting, this chair has also the drawbacks of loading the area of knees as they receive a great part of the body's load and of constraining the legs' movements. On the other hand, it enforces a lumbar lordosis very close to the one adopted while standing and does not constrain the torso to move freely forward, backward, or sideways.

There are quite a lot of detailed ergonomic requirements concerning the design of seats used at work. For example:

- The seat should be adjustable in order to fit to the various anthropometric characteristics of their users as well as to different working heights.
- The seat should offer stability to the user.
- The seat should offer freedom of movement to the user.
- The seat should be equipped with armrests.
- The seat lining material should be water absorbent to absorb body perspiration.

The detailed requirements will not be presented extensively here, as the interested reader can find them

**Figure 5**  Lordotic and kyphotic postures of the spine (Grandjean, 1987).

**Figure 6**  Example of a kneeling chair (source: www.comcare.gov.au/officewise.html).

easily in any specialized handbook. Furthermore, these requirements became "classical" and have been adopted by regulatory documents such as health and safety or design standards, legislation, and so on [e.g., European standard EN 1335, International Organization for Standardization (ISO) 9241, American National Standards Institure (ANSI)/HFS 100-1988, and the German standard DIN 4543 for office work or EN 1729 for chairs and tables for educational institutions and ISO/DIS 16121 for the driver's workplace in line-service buses].

Although most of the modern seats for office work meet the basic ergonomics requirements, the design of their controls does not meet the usability principles. This fact, combined with the poor users' knowledge on healthy sitting, results in the nonuse of the adjustment possibilities offered by the seats (Vitalis et al., 2000). Lueder (1986) provides the following guidelines for increasing the usability of controls:

- Controls should be easy to find and interpret.
- Controls should be easily reached and adjusted from the standard seated work position.
- Controls should provide immediate feedback (e.g., seats that adjust in height by rotating pan delay feedback because user must get up and down repeatedly to determine the correct position).
- The direction of operation of controls should be logical and consistent with their effect.
- Few motions should be required to use the controls.
- Adjustments should require the use of only one hand.
- Special tools should not be necessary for the adjustment.
- Labels and instructions on the furniture should be easy to understand.

However, modern office chairs are still far from meeting satisfactorily the above guidelines (Groenesteijna et al., 2009).

## 2.2 Sitting Posture and Work Surface Height

Besides the problem of lumbar kyphosis, sitting working posture may also provoke excessive muscle strain at the level of the back and the shoulders. For example, if the working surface is too low, the person will bend forward too far; if it is too high, he or she will be forced to raise the shoulders.

To minimize these problems, appropriate design of the workplace is required. More specifically, the working surface should be at a height that permits a person to work with the shoulders at the relaxed posture. It should be noticed here that the working height does not always equate to the work surface height. The former depends on what one is working on (e.g., the keyboard of a computer), while the later is the height of the upper surface of the table, desk, bench, and so on. Furthermore, to define the appropriate work surface height, one should consider the angles between the upper arms and the

elbows and the angle between the elbows and the wrists. To increase comfort and minimize the occupational risks, the first of the two angles should be about 90° if no force is required and a little bit broader if application of force is required. The wrists should be straight as far as possible in order to avoid carpal tunnel syndrome.

Two other common problems encountered by people working in the sitting posture are neck aches and dry-eye syndrome. These problems are related to the prolonged gazing at objects placed too high, for example, when the visual display terminal of a computer workstation is placed too high (Ankrum, 1997). The research which aims at determining the optimal placement of such objects, considering the mechanisms of both the visual and musculoskeletal systems, is still active (for a review see Ankrum and Nemeth, 2000). However, most research findings agree that (i) neck flexion is more comfortable than extension, with the zero point (dividing flexion from extension) described as the posture of the head/neck when standing erect and looking at a visual target 15° below eye level, and (ii) the visual system prefers downward gaze angles. Furthermore, there is evidence that when assuming an erect posture, people prefer to tilt their head, with the ear–eye line (i.e., the line which crosses by the cartilaginous protrusion in front of the ear hole and the outer slit in the eyelid) being about 15° below the horizontal plane (Grey et al., 1966; Jampel and Shi, 1992). Based on these findings many authors propose the following rule of thumb for the placement of the monitor: The center of the monitor should be placed at a minimum of 15° below the eye level, with the top and the bottom at an equal distance from the eyes. (i.e., the screen plane should be facing slightly upward).

Sanders and McCormick (1992) propose in addition the following general ergonomics recommendations for work surfaces:

- If at all possible the work surface height should be adjustable to fit individual physical dimensions and preferences.
- The work surface should be at a level that places the working height at elbow height, with shoulders at relaxed posture.
- The work surface should provide adequate clearance for a person's thighs under the work surface.

## 2.3 Spatial Arrangement of Work Artifacts

While working one uses a number of artifacts, for example, the controls and displays on a control panel, the different parts of an assembled object at an assembly workstation, or the keyboard, the mouse, the visual display terminal, the hard-copy documents, and the telephone at an office workstation. Application of the following ergonomic recommendations for the arrangement of these artifacts helps to decrease workload, facilitate the work flow, and improve overall performance (adapted from Sanders and McCormick, 1992):

- *Frequency of Use and Criticality*. Artifacts that are frequently used or are of special importance

should be placed in prominent positions, for example, in the center of the work surface or near the right hand for right-hand people and vice versa for left-hand people.

- *Sequential Consistency*. When a particular procedure is always executed in a sequential order, the artifacts involved should be arranged according to this order.
- *Topological Consistency*. Where the physical location of controlled elements is important for the work, the layout of the controlling artifacts should reflect the geographical arrangement of the former.
- *Functional Grouping*. Artifacts (e.g., dials, controls, visual displays) that are related to a particular function should be grouped together.

Application of the above recommendations requires detailed knowledge of the task demands. Task analysis provides enough data to appropriately apply these recommendations as well as solve eventual contradictions between them by deciding which arrangement best fits the situation at hand.

## 3  DESIGNING INDIVIDUAL WORKSTATIONS

Figure 7 presents a generic process for the design of individual workstations, with the various phases, the data or sources of data to be considered at each phase, and methods that could be applied. It has to be noted that certain phases of the process may be carried out concurrently or in a different order depending on the particularities of the workstation to design or the preferences and experience of the designers.

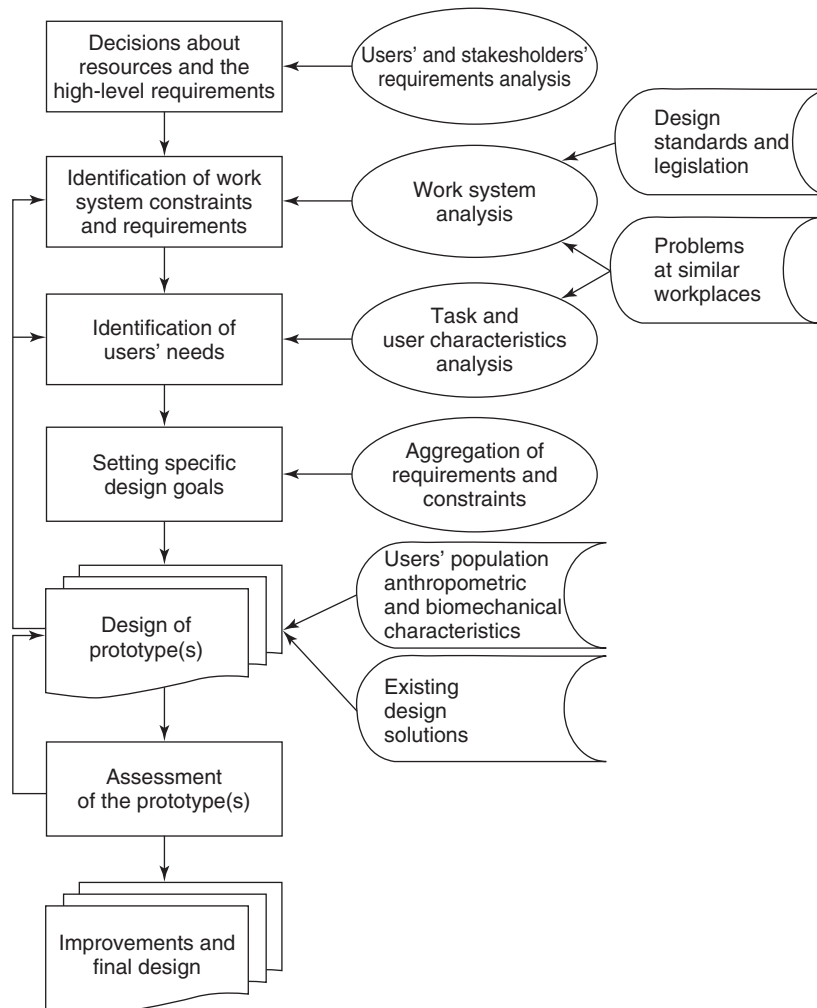

**Figure 7**  Generic process for the ergonomic design of individual.

### 3.1 Phase 1: Decisions about Resources and High-Level Requirements

The aim of the first phase of the design process is to decide the time to spend and the people who will participate in the design team. These decisions depend on the high-level requirements of the stakeholders (e.g., improvement of working conditions, increase of productivity, innovation, occupational safety and health protection) as well as the money they are ready to spend and the importance of the project (e.g., number of identical workstations, significance of the tasks carried out, special characteristics of the working persons). An additional issue that has to be dealt with in this phase is to ensure participation in the design team of representatives of the people who will occupy the future workstations. The access to workstations where similar jobs are being performed is also advisable.

The rest of the design process will be significantly influenced by the decisions made in this phase.

### 3.2 Phase 2: Identification of Work System Constraints and Requirements

The aim of this phase is to identify the different constraints and requirements imposed by the work system in which the workstation will be installed. More specifically, during this phase the design team has to collect data about:

- Types of tasks to be carried out at the workstation
- Work organization, for example, working hours, interdependencies between the tasks to be carried out at the workstation, and other tasks or organizational entities in the proximal environment
- Various technological equipment and tools that will be used, their functions and manipulation, their shape and dimensions, and user interfaces
- Environmental conditions of the broader area in which the workstation will be installed (e.g., illumination and sources of light, level of noise and noise sources, thermal conditions, and sources of warm or cold draughts)
- Normal as well exceptional situations in which the working persons could be found (e.g., electricity breakdowns, fire)
- Any other element or situation of the work system that may directly or indirectly interfere with the workstation

These data can be collected by questioning the appropriate people as well as observation and analysis of similar work situations. Specific design standards (e.g., ANSI, EC, DIN, or ISO) as well as legislation related to the type of the workstation designed should also be collected and studied in this phase.

### 3.3 Phase 3: Identification of Users' Needs

The needs of the future workstation users are identified during this phase, considering their task demands as well as their specific characteristics. Consequently, task analysis (see Chapter 13) and users' characteristics analysis should be carried out in this phase.

The task analysis aims at identifying mainly:

- Work processes that will take place and the workstation elements implicated in them
- Physical actions that will be carried out, for example, fine manipulations, whole-body movement, and force exertion
- Required information exchange (visual, auditory, kinesthetic, etc.) and the information sources providing them
- Required privacy
- Required proximity with other workstations, equipment, or elements of the proximal working environment

The observation and analysis of existing work situations with similar workstations may provide valuable information about the users' needs. In fact, as Leplat (2006) points out, work activity is a complex process which comprises essential dynamic and temporal aspects and which integrates the effect of multiple constraints and demands. It should be distinguished from behavior that only constitutes its observable facet: Activity includes behavior and its regulating mechanisms (Leplat, 2006). Although work activity can operationally be described from many views using diverse models, its most fundamental characteristic is that it should be studied intrinsically as an original construction by the workers (Daniellou and Rabardel, 2005; Nathanael and Marmaras, 2009). Therefore, users' needs cannot be fully identified by a simple task analysis.

The specific characteristics of the users' population may include their gender, age, particular disabilities, previous experiences and work practices, and cultural or religious obligations (e.g., in certain countries women are obliged to wear particular costumes).

At this phase, data about performance and health problems of persons working in similar work situations should also be collected. Literature related to ergonomics and to occupational safety and health may be used as the main source for the collection of such data [see the websites of the U.S. Occupational Safety and Health Administration (http://www.osha.gov) and the European Organization of Occupational Safety and Health (http://osha.europa.eu)].

Finally, as in the previous phase, the users' needs should be identified not only for normal but also for exceptional situations in which the workstation occupants may be found (e.g., working under stress, electricity blackout, fire).

### 3.4 Phase 4: Setting Specific Design Goals

Considering the outputs of the previous phases, the design team can now transform the generic ergonomics requirements of workstation design into a set of specific goals. These specific design goals will guide the choices and the decisions to be made in the next phase. Furthermore, they will be used as criteria for assessing the designed prototype and will guide its improvement.

The specific goals are an aggregation of *shoulds* and consist of:

- Requirements of the stakeholders (e.g., the workstation should be convenient for the 95% of the user population, should cost a maximum of $X$ dollars, should increase productivity at least 10%)
- Constraints and requirements imposed by the work system in which the designed workstation(s) will be installed (e.g., the workstation should not exceed $X$ centimeters of length and $Y$ centimeters of width, should offer working conditions not exceeding $X$ decibels of noise and $Y$ degrees of wet bulb globe temperature)
- Users' needs (e.g., the workstation should accommodate elderly people, should be appropriate for prolonged computer work, should facilitate cooperation with the neighboring workstations, should permit the alteration of sitting and standing postures)
- Requirements to avoid common health problems associated with similar situations (e.g., the workstation should minimize upper limb musculoskeletal problems)
- Design standards and related legislation (e.g., the workstation should ensure absence of glare or cold draughts)

The systematic record of all the specific design goals is very helpful for the next phases. It is important to note that agreement on these specific goals between the design team, the management, and user representatives is indispensable.

### 3.5   Phase 5: Design of Prototype

This phase is the most demanding of the design process. In fact, the design team has to generate design solutions meeting all the specific design goals identified in the previous phase. Due to the large number of design goals, as well as the fact that some of them may be conflicting, the design team has to make appropriate compromises, considering some goals as more important than others and eventually passing by some of them. As already stated, good knowledge of the task demands and users' needs, as well as the specific users' characteristics, is the only way to set the right priorities and avoid serious mistakes. Furthermore, the use of data related to (i) the size of the body parts (anthropometry, see Chapter 11) and (ii) the ability and limits of their movements (biomechanics, see Chapter 12) of the users' population should be considered in this phase.

A first decision to make is the working posture(s) that will assume the users of the workstation. Table 1 provides some recommendations for this.

Once the working posture has been decided, the design may continue to define the shape, the dimensions, and the arrangement of the various elements of the workstation. To do so, one has to consider the anthropometric and biomechanical characteristics of the users'

**Table 1  Recommendations for Choosing Working Posture**

| Working posture | Task requirements |
|---|---|
| Working person's choice | It is preferable to arrange for both sitting and standing (see Figure 4) |
| Sitting | Where a stable body is needed:<br>• For accurate control, fine manipulation<br>• For light manipulation work (continuous)<br>• For close visual work — with prolonged attention<br>• For limited headroom, low work heights<br>Where foot controls are necessary (unless of infrequent or short duration)<br>Where a large proportion of the working day requires standing |
| Standing | For heavy, bulky loads<br>Where there are frequent moves from the workplace<br>Where there is no knee room under the equipment<br>Where there is limited front–rear space<br>Where there is a large number of controls and displays<br>Where a large proportion of the working day requires sitting |
| Support seat (see Figure 8) | Where there is no room for a normal seat but a support is desirable |

*Source*: (Corlett and Clark, 1995)

Footrest

**Figure 8**   Example of support seat (Helander, 1995).

population as well as the working actions that will be performed. Besides the ergonomics recommendations presented in previous sections, some additional recommendations for the design of the workstation are the following:

- To define the *clearance*, that is, the minimum required free space for placement of the various body parts, one has to consider the largest user (usually the anthropometric dimensions corresponding to the 97.5 percentile). In fact, providing free space for these users, all shorter users will also have enough space to place their body. For example, if the vertical, lateral, and forward clearances below the working desk are designed considering the height of the thigh upper surface for a sitting person, the hip width and the thigh length corresponding to the 97.5 percentile of the users' population (plus 1 or 3 cm for allowance), 97.5% of the users of this desk will be able to easily approach the desk while sitting.

- To position the different elements of the workplace that must be *reached* by the users, consider the smaller user (usually the anthropometric dimensions corresponding to the 2.5 percentile). In fact, if the smaller users easily reach the various workstation elements, that is, without leaning forward or bending sideways, all larger users will also easily reach them.

- Draw the common kinetospheres or comfort zones for the larger and smaller users and include the various elements of the workstation that have to be manipulated (e.g., controls) (Figure 9).

- When necessary, provide the various elements of the workstation with appropriate adjustability in order to fit in the anthropometric characteristics of the users' population. In this case, it is important to ensure the usability of the corresponding controls.

- While envisioning design solutions continuously check to ensure that the workstation elements do not obstruct the users' courses of action (e.g., perception of necessary visual information, manipulation of controls).

It should be stressed that at least some iterations between phases 2, 3, and the present phase of the design process are unavoidable. In fact, it is almost impossible to identify from the start all the constraints and requirements of the work system, the users' characteristics, or the task requirements that intertwine with the elements of the anticipated workstation.

Another issue to deal with in this phase is designing for protection of the working person from possible annoying or hazardous environmental factors. If the workstation has to be installed in a harsh environment (noisy, cold, or warm, in a hazardous atmosphere, etc.), one has to provide appropriate protection. Again, attention should be paid to the design of such protective elements. These should take into consideration the anthropometric characteristics of the users' population and the task demands in order not to obstruct the processes involved in both normal and degraded operation (e.g., maintenance, breakdowns).

Other important issues that have to be resolved in this phase are the workstation maintainability, its unrestricted evacuation, its stability, and robustness as well as other safety issues such as rough corners.

The search for already existing design ideas and solutions is quite useful. However, they should be carefully examined before their adoption. In fact, such design ideas, although valuable for anticipation, may not be readily applicable for the specific users' population, the specific task demands, or the environment in which the workplace will be installed. Furthermore, many existing design solutions may disregard important ergonomics issues. Finally, although the adoption of already existing design solutions exploits the design community's experience and saves time, it deprives the design team of generating innovative solutions.

The use of computer-aided design (CAD) software with human models is very helpful in this phase. If such software is not available, appropriate drawings and

**Figure 9** Drawing the common comfort zones of hands and legs for the large and small users of a driving workplace with nonadjustable chair.

mock-ups should be developed for the generation of design solutions as well as for their assessment (see next phase).

Given the complexity of generating good design solutions, the search for alternatives is useful. The members of the design team should not be anchored at the first design solution that comes to their minds. They should try to generate as many alternative ideas as possible, gradually converging on the ones that better satisfy the design goals.

### 3.6 Phase 6: Assessment of Prototype

Assessment of the designed prototype(s) is required in order to check how well the specific design goals, set in phase 4, have been met, as well as to uncover possible omissions during the identification of the work system constraints and requirements and the users' needs analysis (phases 2 and 3).

The assessment can be performed analytically or/and experimentally, depending on the importance of the project. In the analytical assessment the design team assesses the designed workplace considering exhaustively the specific design goals using the drawings and mock-ups as support. Applying a multi criteria method, the design team may rank the degree to which the design goals have been met. This ranking may be used as a basis for the next phase of the design process (improvement of the prototype) as well as a means to choose among alternative design solutions.

The experimental assessment (or user testing) is performed with the participation of a sample of future users, simulating the work with a full-scale mock-up of the designed workstation prototype(s). The assessment should be made in conditions as close as possible to the real work. Development of use scenarios of both normal and exceptional work situations is useful for this reason. Experimental assessment is indispensable for the identification of problematic aspects that are difficult, if not impossible, to realize before having a real workplace with real users. Furthermore, this type of assessment provides valuable insights for eventual needs during implementation (e.g., the training needed, the eventual need for a users' manual).

### 3.7 Phase 7: Improvements and Final Design

In this phase, the design team proceeds with the required modifications of the designed prototype, considering the outputs of the assessment. The opinions of other specialists such as architects and decorators which have more to do with the aesthetics or production engineers and industrial designers which have more to do with production or materials and robustness matters should be considered in this phase (if such specialists are not already part of the design team).

The final design should be complemented with:

- Drawings for production and appropriate documentation, including the rationale behind the adopted solutions
- Cost estimation for the production of the workstation(s) designed

- Implementation requirements such as the training needed and the users' manual, if required

### 3.8 Final Remark

The reason for conducting the users' needs and requirements analysis is to anticipate the future work situation in order to design a workstation that fits its users, their tasks, and the surrounding environment. However, it is impossible to completely anticipate a future work situation in all its aspects, as work situations are complex, dynamic, and evolving. Furthermore, if the workstation is destined to form part of an already existing work system, it might affect the overall work ecology, something which is also very difficult to anticipate. Therefore, a number of modifications will eventually be needed some time after installation and use. Thus it is strongly suggested to conduct a new assessment of the designed workstation once the users have been familiarized with the new work situation.

## 4 LAYOUT OF WORKSTATIONS

Layout deals with the placement and orientation of individual workstations in a given space (building). The main ergonomics requirements concern the tasks performed, the work organization, and the environmental factors:

- The layout of the workstations should facilitate the work flow.
- The layout of the workstations should facilitate cooperation (of both personnel and external persons, e.g., customers).
- The layout of the workstations should conform to the organizational structure.
- The layout should ensure the required privacy.
- There should be appropriate lighting, conforming to the task's and working person's needs.
- The lighting should be uniform throughout the working person's visual field.
- There should be no annoying reflections or glare in the working area.
- There should be no annoying hot or cold draughts in the workplace.
- Access to the workstations should be unobstructed and safe.

In this section we will focus on the layout of workplaces for office work for the following reasons: First, office layout is an exemplar case for the arrangement of a number of individual workstations in a given space, encompassing all the main ergonomics requirements found in most types of workplaces (with the exception of workplaces where the technology involved determines to a large extent the layout, e.g., workstations in front of machinery). Second, office workplaces concern a growing percentage of the working population worldwide. For example, during the twentieth century the percentage of office workers increased from 17% to over 50% of the workforce in the United States, the rest

working in agriculture, sales, industrial production, and transportation (Czaja, 1987). With the spread of information technologies, the proportion of office workers is expected to further increase; in fact, Brounen and Eichholtz (2004) and Veitch et al. (2007) estimate that at least 50% of the world's population currently works in some form of office. Third, there are still a significant number of office workers which suffer from musculoskeletal disorders or other work-related problems (Corlett, 2006; Griffiths et al., 2007; Luttmann et al., 2010). Finally, current health problems encountered by office workers are to a great extent related to the inappropriate layout of their workplaces (Marmaras and Papadopoulos, 2002).

## 4.1 Generic Types of Office Layouts

There is a number of generic types of office layouts (Shoshkes, 1976; Zelinsky, 1998). The two extremes are the "private office," where each worker has his or her personal closed space/room, and the "open plan," where all the workstations are placed in a common space. In between are a multitude of combinations of private offices with open plans. Workstation arrangements in open plans can be either orthogonal, with single, double, or fourfold desks forming parallel rows, or with the workstations arranged in groups, matching the organizational or functional structure of the work. A recent layout philosophy is the "flexible office," where the furniture and the equipment are designed to be easily movable in order to be able to modify the workstation arrangement depending on the number of people present at the office as well as the number of running projects or work schemes (Brunnberg, 2000). Finally, in order to respond to the current needs for flexibility in the organization and structure of enterprises as well as reduce costs, a new trend in office management is the "free address office" or "nonterritorial office," where workers do not have their own workstation but use the workstation they find free whenever at the office.

Each type of layout has its strengths and weaknesses. Private offices offer increased privacy and better control of environmental conditions, fitting to the particular preferences and needs of their users. However, they are more expensive both in construction and maintenance, not easily modifiable to match changing organizational needs, and render cooperation and supervision difficult. Open-plan offices offer flexibility in changing organizational needs and facilitate cooperation between co-workers but tend to suffer from environmental annoyances such as noise and suboptimum climatic conditions as well as lack of privacy [see De Croon et al. (2005) for a review]. To minimize the noise level and to create some sense of privacy in the open plans, movable barriers may be used. To be effective, the barriers have to be at least 1.5 m high and 2.5 m wide. Furthermore, Wichman (1984) proposes the following specific design recommendations to enhance the working conditions in an open-plan office:

- Use sound-absorbing materials on all major surfaces wherever possible. Noise is often more of a problem than expected.

- Equip the workstations with technological devices of low noise (printers, photocopy machines, telephones, etc.). For example, provide telephones that flash a light for the first two "rings" before emitting an auditory signal.

- Leave some elements of design for the workstation user. People need to have control over their environments; leave some opportunities for changing or rearranging things.

- Provide both vertical and horizontal surfaces for the display of personal belongings. People like to personalize their workstations.

- Provide several easily accessible islands of privacy. This would include small rooms with full walls and doors that can be used for conferences and private or long-distance telephone calls.

- Provide all private work areas with a way to signal willingness of the occupant to be disturbed.

- Have clearly marked flow paths for visitors. For example, hang signs from the ceiling showing where secretaries and department boundaries are located.

- Design workstations so it is easy for drop-in visitors to sit down while speaking. This will tend to reduce disturbances to other workers.

- Plan for ventilation air flow. Most traditional offices have ventilation ducting. This is usually not the case with open-plan cubicles, so they become dead-air cul-de-sacs that are extremely resistant to post hoc resolution.

- Overplan for storage space. Open-plan systems with their emphasis on tidiness seem to chronically underestimate the storage needs of people.

The decision about the generic type of layout should be taken by the stakeholders. The role of the ergonomist here is to indicate the strengths and weaknesses of each alternative in order to facilitate the adoption of the most appropriate type of layout for the specific situation. After this decision has been made, the design team should proceed to the detailed layout of the workstations. The next section describes a systematic method for this purpose.

## 4.2 Systematic Method for Office Layout

This method proposes a systematic way to design workplaces for office work. The method aims at alleviating the design process for arranging the workstations by decomposing the whole problem to a number of stages during which only a limited number of ergonomic requirements are considered. Another characteristic of the method is that the ergonomics requirements to be considered have been converted to design guidelines (Margaritis and Marmaras, 2003). Figure 10 presents the main stages of the method.

Before starting the layout design, the design team should collect data concerning the activities that will be performed in the workplace and the needs of the

Inputs
(data and requirements)                                    Ergonomic requirements

- Walls
- Columns
- Doors                    Determination of              - Easy access to:
- Windows                  space available                 Doors
- Radiators                                                 Windows
- ....                                                      Radiators
                                                            ...

- Desk
- Chairs                   Design of workstation         - Fitting the workstation
- Computer                 modules                         to its users and tasks
- Lockers                                                - Easy access to
- ....                                                     workstations

- Cooperation
- Available surface                                      - Facilitation of cooperation
- Required surface                                         (internal and external)
- Organizational units     Placement of                 - Ensure working conditions
- Already existing         organizational units           meeting task requirements
- closed spaces                                          - Utilization of already existing
- ...                                                      closed spaces

- Organizational units                                   - Facilitation of cooperation
- Cooperation                                              (internal and external)
- Lighting needs                                         - Ensure working conditions
- Privacy needs            Placement of the               meeting task requirements
- External visitors        workstation modules           - Easy access to
- Structural elements                                      the workstations
- ....                                                   - Ensure required privacy
                                                         - ...

- Cooperation                                            - Facilitation of cooperation
- Doors                                                    (internal and external)
- Windows                  Orientation of               - Ensure appropriate
- Supervision              workstation modules            lighting conditions
- ....                                                   - Easy access to
                                                           workstations
                                                         - Facilitation of supervision
                                                         - ...

**Figure 10**   Main stages of a method for office layout meeting the ergonomic requirements.

workers. More specifically, the following information should be gathered:

- The number of people that will work permanently or occasionally.
- The organizational structure and the organizational units it comprises.
- The activities carried out by each organizational unit. Of particular interest are the needs

for cooperation between the different units (and consequently the desired relative proximity between them), the need for reception of external visitors (and consequently the need to provide easy access to them), and any other need related to the particularities of the unit (e.g., security requirements).

- The tasks carried out by each worker. Of particular interest are the needs for cooperation with other workers, the privacy needs, the

reception of external visitors, and the specific needs for lighting.

- The equipment required for each task (e.g., computer, printer, storage).

At this stage the design team should also get the detailed ground plan drawings of the space concerned, including all elements which should be considered as fixed (e.g., structural walls, heating systems).

### 4.2.1 Stage 1: Determination of Available Space

The aim of this stage is to determine the space where no furniture should be placed in order to ensure free passage by the doors and to allow the necessary room for elements such as windows and radiators for manipulation and maintenance purposes.

To determine the free-of-furniture spaces the following suggestions can be used (Figure 11). Allow for

- An area of 50 cm in front of any window
- An area of 3 m in front and 1 m on both sides of the main entrance door
- An area of 1.50 m in front and 50 cm on both sides of any other door
- An area of 50 cm around any radiator

### 4.2.2 Stage 2: Design of Workstation Modules

The aim of this stage is to design workstation modules that meet the needs of the workers. Each module is composed of the appropriate elements for the working activities, that is, desk, seat, storage cabinets, visitors' seats, and any other equipment required for the work. A free space should be provided around the furniture for passages between the workstations as well as for unobstructed sitting and getting up from the seat. This free space may be delimited in the following way (minimum areas).

Allow for:

- An area of 55 cm along the front side of the desk or the outer edge of the visitor's seat
- An area of 50 cm along the entry side of the workstation
- An area of 75 cm along the back side of the desk (seat side)
- An area of 100 cm along the back side of the desk if there are storage cabinets behind the desk

A number of different modules will result from this stage, depending on the particular work requirements (e.g., secretarial module, head of unit module, client service module) (Figure 12).

**Figure 12** Examples of workstation modules.

**Figure 11** Determining the available space.

Laying out workstation modules instead of individual elements such as desks, seats, and so on, permits the designer to focus on the requirements related to the overall layout of the workplace, at the same time ensuring compliance with the requirements related to the individual workstations.

### 4.2.3 Stage 3: Placement of Organizational Units

The aim of this stage is to decide the placement of the different organizational units (i.e., departments, working teams, etc.) within the various free spaces of the building. There are five main issues to be considered here: (i) the shape of each space, (ii) the exploitable area of each space, that is, the area where workstations can be placed, (iii) the required area for each unit, (iv) the desired proximity between the different units, and (v) eventual particular requirements of each unit which may determine their absolute placement within the building (e.g., the reception should be placed right next to the main entrance).

The exploitable area of each space is an approximation of the "free-of-furniture spaces" defined in the first stage, considering also narrow shapes where modules cannot fit. Specifically, this area can be calculated as follows:

$$A_{\text{exploitable}} = A_{\text{total}} - A_{\text{where no modules can be placed}}$$

where

$$A_{\text{total}} = \text{total area of each space}$$
$$A_{\text{where no modules can be placed}} = \text{nonexploitable area, where workstation modules should not or cannot be placed}$$

The required area for each organizational unit can be estimated considering the number of workstation modules needed and the area required for each module. Specifically, in order to estimate the required area for each organizational unit, $A_{\text{required}}$, one has to calculate the sum of the areas of the different workstation modules of the unit.

Comparing the exploitable area of the different spaces with the required area for each unit, the candidate spaces for placing the different units can be defined. Specifically, the candidate spaces for the placement of a particular unit are the spaces where

$$A_{\text{exploitable}} \geq A_{\text{required}}$$

Once the candidate spaces for each unit have been defined, the final decisions about the placement of organizational units can be made. This is done in two steps. In the first step the designer designates spaces for eventual units which present particular placement requirements (e.g., reception). In the second step he or she positions the remaining units considering their desirable relative proximity plus additional criteria such as the need for natural lighting or the reception of external visitors. To facilitate the placement of the organizational units according to their proximity requirements, a *proximity table* as well as *proximity diagrams* may be used.

The *proximity table* represents the desired proximity of each unit with any other one, rated by using the following scale:

**9**: The two units cooperate firmly and should be placed close together.

**3**: The two units cooperate from time to time, and it would be desirable to place them in proximity.

**1**: The two units do not cooperate frequently, and it is indifferent if they will be placed in proximity.

Figure 13 presents the proximity table of a hypothetical firm consisting of nine organizational units. At the right bottom of the table, the total proximity rate (TPR) has been calculated for each unit as the sum of its individual proximity rates. The TPR is an indication of the cooperation needs of each unit with all the others. Consequently, the designer should try to place the units with high TPRs at a central position.

*Proximity diagrams* are a graphical method for the relative placement of organizational units. They facilitate the heuristic search for configurations which minimize the distance between units with close cooperation. Proximity diagrams are drawn on a sheet of paper with equidistant points, like the one shown at Figure 14. The different units are alternated at the different points, trying to find arrangements where the units with close cooperation will be as close as possible to each other.

**Figure 13**  Proximity table of a hypothetical firm.

**Figure 14**   Example of a proximity diagram.

The following rules may be applied to obtain a first configuration:

- Place the unit with the highest TPR at the central point.
- If more than one unit has the same TPR, place the unit with the closest proximity rates (9's) first.
- Continue placing the units having the higher proximity rates with the ones that have already been positioned.
- If more than one unit has proximity rates equal to the one already positioned, place the unit with the higher TPR first.
- Continue in the same manner until all the units have been positioned.

More than one alternative arrangement may be obtained in this way. It should be noted that the proximity diagrams are drawn without taking into account the required area for each unit and the exploitable area of the spaces where the units may be placed. Consequently, the arrangements drawn cannot be directly transposed to the ground plan of the building without modifications. Drawing the proximity diagrams is a means of facilitating the decision concerning the relative positions between organizational units. This method becomes useful when the number of units is high.

### 4.2.4   Stage 4: Placement of Workstation Modules

Considering the outputs of the previous stage, placement of the workstation modules of each unit can start. The following guidelines provide help in meeting the ergonomic requirements:

1.  Place the workstations in a way that facilitates cooperation between co-workers. In other words, workers who cooperate tightly should be placed near each other.
2.  Place the workstations which receive external visitors near the entrance doors.
3.  Place as many workstations as possible near the windows. Windows may provide benefits besides variety in lighting and a view (Hall, 1966). They permit fine adjustment of light through curtains or venetian blinds and provide distant points of visual focus, which can relieve eye fatigue. Furthermore, related research has found that people strongly prefer the workstations placed near windows (Manning, 1965; Sanders and McCormick, 1992).
4.  Avoid placing the working persons in airstreams created by air conditioners, open windows, and doors.
5.  Place the workstation modules in a way that forms straight corridors leading to the doors. Corridors widths for one-person passage should be at least 60 cm and for two-person passage at least 120 cm (Alder, 1999).
6.  Leave the required space in front and to the sides of electric switches and wall plugs.
7.  Leave the required space for waiting visitors. In cases where waiting queues are expected, provide at least a free space of 120 cm width and $n \times 45$ cm length, where $n$ is the maximum expected number of waiting people. Add to this length another 50 cm in front of the queue.

### 4.2.5   Stage 5: Orientation of Workstation Modules

The aim of this stage is to define the direction of the workstation modules of each unit to meet the

**Figure 15**   Workstations with VDT ideally should be placed at right angles to the windows.
**Figure 16**  Alternative orientations of workstations, depending on the number of team members and the presence or not of a leader. Ia, Ib, and Ic: arrangements with leader; IIa, IIb, and IIc: arrangements without leader.

ergonomics requirements. This stage can be carried out either concurrently with or after the previous stage. The following guidelines may be applied, making appropriate trade-offs if all of them cannot be satisfied:

1. Orient the workstations in such a way that there are no windows directly in front or behind the workers when they are looking toward a visual display terminal (VDT). In offices, windows play a role similar to lights: A window right in front of a worker disturbs through direct glare while directly behind produces reflected glare. For this reason VDT workstations ideally should be placed at right angles to the windows (Grandjean, 1987). (Figure 15).

2. Orient the workstations in such a way that there are no direct lighting sources within ±40° in the vertical and horizontal directions from the line of sight in order to avoid direct glare (Kroemer et al., 1994).

3. Orient the workstations in a way that allows workers to observe entrance doors.

4. Orient the workstations so as to facilitate cooperation between members of work teams. Figure 16 shows alternative orientations of workstations, depending on the number of team members and the presence or not of a leader (Cummings et al., 1974).

## 4.3  Concluding Remarks

Given the complexity of workplace layout design, the design team, trying to apply the various ergonomics guidelines in the different phases, will almost definitely encounter contradictions. To resolve them the design team should be able to focus on the ones considered more important for the case at hand and pay less attention or eventually neglect others. Good knowledge of the generic human abilities and limitations, the

specific characteristics of the people who will work in the designed workplace, and the specificities of the work which will be carried out by them is a prerequisite for successful decisions. Furthermore, the members of the design team should have open and innovative minds and try as many solutions as possible. A systematic assessment of these alternative solutions is advisable to decide on the most satisfactory solution. The participation of the different stakeholders in this process is strongly recommended.

The use of specialized CAD tools may prove very helpful for the application of the presented method, greatly facilitating the generation and assessment of alternative design solutions.

# CHAPTER 22

# VIBRATION AND MOTION

**Michael J. Griffin**
**Human Factors Research Unit, Institute of Sound and Vibration Research**
**University of Southampton**
**Southampton, England**

## 1 INTRODUCTION

In work and leisure activities the human body experiences movement. The motion may be voluntary (as in some sports) or involuntary (as for passengers in vehicles). Movements may occur simultaneously in six different directions: three translational directions (fore-and-aft, lateral, and vertical) and three rotational directions (roll, pitch, and yaw). Translational movements at constant velocity (i.e., with no change of speed or direction) are mostly imperceptible, except where exteroceptors (e.g., the eyes or ears) detect a change of position relative to other objects. Translational motion can also be detected when the velocity changes, causing acceleration or deceleration of the body that can be perceived via interoceptors (e.g., the vestibular, cutaneous, kinesthetic, or visceral sensory systems). Rotation of the body at constant velocity may be detected because it gives rise to translational acceleration in the body, because it re-orientates the body relative to the gravitational force of Earth, or because the changing orientation relative to other objects is perceptible through exteroceptors. Vibration is oscillatory motion: the velocity is changing and so the movement is detectable by interoceptors and exteroceptors.

Vibration of the body may be desirable or undesirable. It can be described as pleasant or unpleasant, it can interfere with the performance of various tasks and cause injury and disease. Low-frequency oscillations of the body and movements of visual displays can cause motion sickness. It is convenient to consider human exposure to oscillatory motion in three categories:

1. *Whole-body vibration* occurs when the body is supported on a surface that is vibrating (e.g., sitting on a seat that vibrates, standing on a vibrating floor or lying on a vibrating surface). Whole-body vibration occurs in transport (e.g., road, off-road, rail, air and marine transport) and when near some machinery.

2. *Motion sickness* can occur when real or illusory movements of the body or the environment lead to ambiguous inferences as to the movement or orientation of the human body. The movements associated with motion sickness are always of very low frequency, usually below 1 Hz.

3. *Hand-transmitted vibration* is caused by various processes in industry, agriculture, mining, construction, and transport where vibrating tools or workpieces are grasped or pushed by the hands or fingers.

There are many different effects of oscillatory motion on the body and many variables influencing each effect. The variables may be categorized as extrinsic variables (those occurring outside the human body) and intrinsic variables (the variability that occurs between

**Table 1 Variables Influencing Human Responses to Oscillatory Motion**

| Extrinsic variables | Intrinsic variables |
|---|---|
| Vibration variables: | Intrasubject variability |
|   Vibration magnitude |   Body posture |
|   Vibration frequency |   Body position |
|   Vibration direction |   Body orientation (sitting, |
|   Vibration input positions |     standing, recumbent) |
|   Vibration duration | Intersubject variability |
| Other variables: |   Body size and weight |
|   Other stressors (noise, |   Body dynamic response |
|     temperature, etc.) |   Age |
|   Seat dynamics |   Gender |
| |   Experience, expectation, |
| |     attitude, and personality |
| |   Fitness |

**Figure 1** Displacement, velocity, and acceleration waveforms for a sinusoidal vibration. If the vibration has frequency $f$ (in hertz) and peak displacement $D$ (in meters), the peak velocity is $V = 2\pi f D$ (in meters per second) and the peak acceleration is $A = (2\pi f)^2 D$ (in meters per second per second).

and within people), as in Table 1. Some variables, especially intersubject variability, have large effects but are not easily measured. Consequently, it is often not practicable to make highly accurate predictions of the discomfort, interference with activities, or health effects for an individual. However, the average effect, or the probability of an effect, can be predicted for groups of people.

This chapter introduces human responses to oscillatory motion, summarizes current methods of evaluating exposures to oscillatory motion, and identifies some methods of minimizing unwanted effects of vibration.

## 2 MEASUREMENT OF VIBRATION AND MOTION

### 2.1 Vibration Magnitude

When vibrating, an object has alternately a velocity in one direction and then a velocity in the opposite direction. This change in velocity means that the object is constantly accelerating, first in one direction and then in the opposite direction. Figure 1 shows the displacement waveform, the velocity waveform, and acceleration waveform for a movement occurring at a single frequency (i.e., a sinusoidal oscillation). The magnitude of a vibration can be quantified by its displacement, its velocity, or its acceleration. For practical convenience, the magnitude of vibration is now usually expressed in terms of the acceleration and measured using accelerometers. The units of acceleration are meters per second per second (i.e., m s$^{-2}$, or m/s$^2$). The acceleration due to gravity on Earth is approximately 9.81 m s$^{-2}$.

The magnitude of an oscillation can be expressed as the difference between the maximum and minimum values of the motion (e.g., the peak-to-peak acceleration) or the maximum deviation from some central point (e.g., the peak acceleration). Most often, magnitudes of vibration are expressed in terms of an average measure of the oscillatory motion, usually the root-mean-square (r.m.s.) value of the acceleration (i.e., m s$^{-2}$ r.m.s. for
translational acceleration, rad s$^{-2}$ r.m.s. for rotational acceleration). For a sinusoidal motion, the r.m.s. value is the peak value divided by $\sqrt{2}$ (i.e., the peak value divided by approximately 1.4).

When observing vibration, it is sometimes possible to estimate the displacement caused by the motion. For a sinusoidal motion, the acceleration $a$ can be calculated from the frequency $f$ in hertz and the displacement $d$:

$$a = (2\pi f)^2 d$$

For example, a sinusoidal motion with a frequency of 1 Hz and a peak-to-peak displacement of 0.1 m will have an acceleration of 3.95 m s$^{-2}$ peak to peak, 1.97 m s$^{-2}$ peak, and 1.40 m s$^{-2}$ r.m.s. Although this expression can be used to convert acceleration measurements to corresponding displacements, it is only accurate when the motion occurs at a single frequency (i.e., it has a sinusoidal waveform as shown in Figure 1).

Logarithmic scales for quantifying vibration magnitudes in decibels are sometimes used. When using the reference level in International Standard 1683 [International Organization for Standardization (ISO), 2008], the acceleration level $L_a$ is expressed by $L_a = 20 \log_{10}(a/a_0)$, where $a$ is the measured acceleration (in m s$^{-2}$) and $a_0$ is the reference level of $10^{-6}$ m s$^{-2}$. With this reference, an acceleration of 1 m s$^{-2}$ corresponds to 120 dB, and an acceleration of 10 m s$^{-2}$ corresponds to 140 dB.

### 2.2 Vibration Frequency

The frequency of vibration is expressed in cycles per second using the SI unit hertz (Hz). The frequency of vibration influences the extent to which vibration is transmitted to the surface of the body (e.g., through seating), the extent to which it is transmitted through the body (e.g., from seat to head), and the responses to vibration within the body. From Section 2.1 it will be seen that the relation between the displacement and the

acceleration of a motion depends on the frequency of oscillation: A displacement of 1 mm corresponds to a low acceleration at low frequencies (e.g., 0.039 m s$^{-2}$ at 1 Hz) but a very high acceleration at high frequencies (e.g., 394 m s$^{-2}$ at 100 Hz).

### 2.3   Vibration Direction

The responses of the body to motion differ according to the direction of the motion. Vibration is often measured at the interfaces between the body and the vibrating surfaces in three orthogonal directions. Figure 2 shows a coordinate system used when measuring vibration of a hand holding a tool.

The three principal directions of whole-body vibration for seated and standing persons are $x$ axis (fore-and-aft), $y$ axis (lateral), and $z$ axis (vertical). The vibration is measured at the interface between the body and the surface supporting the body (e.g., on the seat beneath the ischial tuberosities for a seated person, beneath the feet for a standing person). Figure 3 illustrates the translational and rotational axes for an origin at the ischial tuberosities on a seat and the translational axes at a backrest and the feet of a seated person.

**Figure 2**   Axes of vibration used to measure exposures to hand-transmitted vibration.

**Figure 3**   Axes of vibration used to measure exposures to whole-body vibration.

### 2.4   Vibration Duration

Some human responses to vibration depend on the duration of exposure. Additionally, the duration of measurement may affect the measured magnitude of the vibration. The root-mean-square (i.e., r.m.s.) acceleration may not provide a good indication of vibration severity if the vibration is intermittent, contains shocks, or otherwise varies in magnitude from time to time (see, e.g., Section 3.3).

## 3   WHOLE-BODY VIBRATION

Whole-body vibration may affect health, comfort, and the performance of activities. The comments of persons exposed to vibration mostly derive from the sensations produced by vibration rather than certain knowledge that the vibration is causing harm or reducing their performance. Vibration of the whole body is produced by various types of industrial machinery and by all forms of transport (including road, off-road, rail, sea, and air transport).

### 3.1   Vibration Discomfort

The relative discomfort caused by different oscillatory motions can be predicted from measurements of the vibration. For very low magnitude motions it is possible to estimate the percentage of persons who will be able to feel vibration and the percentage who will not be able to feel the vibration. For higher vibration magnitudes, an approximate indication of the extent of subjective reactions is available in a semantic scale of discomfort.

Limits appropriate to the prevention of vibration discomfort vary between different environments (e.g., between buildings and transport) and between different types of transport (e.g., between cars and trucks) and within types of vehicle (e.g., between sports cars and limousines). The design limit depends on external factors (e.g., cost and speed) and the comfort in alternative environments (e.g., competitive vehicles).

#### 3.1.1   Effects of Vibration Magnitude

The absolute threshold for the perception of vertical whole-body vibration in the frequency range 1 to 100 Hz is, very approximately, 0.01 m s$^{-2}$ r.m.s.; a magnitude of 0.1 m s$^{-2}$ will be easily noticeable; magnitudes around 1 m s$^{-2}$ r.m.s. are usually considered uncomfortable; magnitudes of 10 m s$^{-2}$ r.m.s. are usually dangerous. The precise values depend on vibration frequency and the exposure duration and they are different for other axes of vibration (Morioka and Griffin, 2006a,b).

A doubling of vibration magnitude (expressed in m s$^{-2}$) produces, very approximately, a doubling of the sensation of discomfort; the precise increase depends on the frequency and direction of vibration. For many motions, a halving of the vibration magnitude therefore greatly reduces discomfort.

#### 3.1.2   Effects of Vibration Frequency and Direction

The dynamic responses of the body and the relevant physiological and psychological processes dictate that

subjective reactions to vibration depend on the frequency and the direction of vibration. The extent to which a given acceleration will cause a greater or lesser effect on the body at different frequencies is reflected in *frequency weightings*: frequencies capable of causing the greatest effect are given the greatest 'weight' and others are attenuated according to their relative importance.

Frequency weightings for human response to vibration have been derived from laboratory experiments in which volunteer subjects have been exposed to a set of motions having different frequencies. The subjects' responses are used to determine *equivalent comfort contours* (Morioka and Griffin, 2006a). The reciprocal of such a curve forms the shape of the frequency weighting. Figure 4 shows frequency weightings $W_b$ to $W_f$ as defined in British standard 6841 [British Standards Institution (BSI), 1987]. International standard 2631 (ISO, 1997) allows the same weightings for evaluating vibration with respect to comfort but requires the use of $W_k$ in place of the almost identical weighting $W_b$ when evaluating vertical vibration at the seat with respect to health effects. Table 2 defines simple asymptotic (i.e., straight-line) approximations to these weightings and Table 3 shows how the weightings should be applied to the 12 axes of vibration illustrated in Figure 3. [The weightings $W_g$ and $W_f$ are not required to predict vibration discomfort: $W_g$ has been used for assessing interference with activities and is similar to the weighting for vertical vibration in an outdated International Standard (ISO 2631, 1974, 1985); $W_f$ is used to predict motion sickness caused by vertical oscillation; see Section 4.]

In order to minimize the number of frequency weightings, some are used for more than one axis of vibration, with different *axis-multiplying factors* allowing for overall differences in sensitivity between

**Table 2 Asymptotic Approximations to Frequency Weightings, $W(f)$, in British Standard 6841 (BSI, 1987) for Comfort, Health, Activities, and Motion Sickness**

| Weighting Name | Weighting Definition | |
|---|---|---|
| $W_b$ | $0.5 < f < 2.0$ | $W(f) = 0.4$ |
| | $2.0 < f < 5.0$ | $W(f) = f/5.0$ |
| | $5.0 < f < 16.0$ | $W(f) = 1.00$ |
| | $16.0 < f < 80.0$ | $W(f) = 16.0/f$ |
| $W_c$ | $0.5 < f < 8.0$ | $W(f) = 1.0$ |
| | $8.0 < f < 80.0$ | $W(f) = 8.0/f$ |
| $W_d$ | $0.5 < f < 2.0$ | $W(f) = 1.00$ |
| | $2.0 < f < 80.0$ | $W(f) = 2.0/f$ |
| $W_e$ | $0.5 < f < 1.0$ | $W(f) = 1.00$ |
| | $1.0 < f < 80.0$ | $W(f) = 1.00/f$ |
| $W_f$ | $0.100 < f < 0.125$ | $W(f) = f/0.125$ |
| | $0.125 < f < 0.250$ | $W(f) = 1.0$ |
| | $0.250 < f < 0.500$ | $W(f) = (0.25/f)^2$ |
| $W_g$ | $1.0 < f < 4.0$ | $W(f) = (f/4)^{1/2}$ |
| | $4.0 < f < 8.0$ | $W(f) = 1.00$ |
| | $8.0 < f < 80.0$ | $W(f) = 8.0/f$ |

*Note:* $f$ = frequency, Hz; $W(f) = 0$ where not defined.

axes (see Table 3). The frequency-weighted acceleration should be multiplied by the axis-multiplying factor before the component is compared with components in other axes or included in any summation over axes. The r.m.s. value of this acceleration (i.e., after frequency weighting and after being multiplied by the axis-multiplying factor) is sometimes called a *component ride value* (Griffin, 1990).

**Figure 4** Acceleration frequency weightings for whole-body vibration and motion sickness as defined in standards BS 6841 (BSI, 1987) and ISO 2631-1 (ISO, 1997).

**Table 3 Application of Frequency Weightings for Evaluation of Vibration with Respect to Discomfort**

| Input Position | Axis | Weighting | Axis-Multiplying Factor |
|---|---|---|---|
| Seat | $x$ | $W_d$ | 1.0 |
| | $y$ | $W_d$ | 1.0 |
| | $z$ | $W_b$ | 1.0 |
| | $r_x$ (roll) | $W_e$ | 0.63 |
| | $r_y$ (pitch) | $W_e$ | 0.40 |
| | $r_z$ (yaw) | $W_e$ | 0.20 |
| Seat back | $x$ | $W_c$ | 0.80 |
| | $y$ | $W_d$ | 0.50 |
| | $z$ | $W_d$ | 0.40 |
| Feet | $x$ | $W_b$ | 0.25 |
| | $y$ | $W_b$ | 0.25 |
| | $z$ | $W_b$ | 0.40 |

*Note:* $f$ = frequency, Hz; $W(f) = 0$ where not defined.

Vibration occurring in several axes is more uncomfortable than vibration occurring in a single axis. To obtain an *overall ride value*, the '*root-sums-of-squares*' of the component ride values is calculated:

$$\text{Overall ride value} = \left[ \sum (\text{component ride values})^2 \right]^{1/2}$$

Overall ride values from different environments can be compared: a vehicle having the highest overall ride value would be expected to be the most uncomfortable with respect to vibration. The overall ride values can also be compared with the discomfort scale shown in Table 4. This scale indicates the approximate range of vibration magnitudes that are significant in relation to the range of vibration discomfort that might be experienced in vehicles.

**Table 4 Scale of Vibration Discomfort from British Standard 6841 (BSI, 1987) and International Standard 2631 (ISO, 1997)**

| | r.m.s Weighted Acceleration ($ms^{-2}$) | |
|---|---|---|
| | 3.15 | |
| Extremely uncomfortable | 2.5 | |
| | 2.0 | Very uncomfortable |
| | 1.6 | |
| | 1.25 | |
| Uncomfortable | 1.0 | |
| | 0.8 | Fairly uncomfortable |
| | 0.63 | |
| | 0.5 | |
| A little uncomfortable | 0.4 | |
| | 0.315 | Not uncomfortable |
| | 0.25 | |

*Source*: BSI (1987a) and ISO (1997).

### 3.1.3 Effects of Vibration Duration

Vibration discomfort tends to increase with increasing duration of exposure to vibration. The rate of increase may depend on many factors, but a simple *fourth-power* time dependency is used to approximate how discomfort varies with duration of exposure from the shortest possible shock to a full day of vibration exposure [i.e., $(\text{acceleration})^4 \times \text{duration} = \text{constant}$; see Section 3.3].

## 3.2 Interference with Activities

Vibration and motion can interfere with the acquisition of information (e.g., by the eyes), the output of information (e.g., by hand or foot movements), or the complex central processes that relate input to output (e.g., learning, memory, decision making). Effects of oscillatory motion on human performance may impair safety.

There is most evidence of whole-body vibration affecting performance for input processes (mainly vision) and output processes (mainly continuous hand control). In both cases there may be a disturbance occurring entirely outside the body (e.g., vibration of a viewed display or vibration of a hand-held control), a disturbance at the input or output (e.g., movement of the eye or hand), and a disturbance within the body affecting the peripheral nervous system (i.e., afferent or efferent nervous system). Central processes may also be affected by vibration, but understanding is currently too limited to make confident generalized statements (see Figure 5).

The effects of vibration on vision and manual control are most usually caused by the movement of the affected part of the body (i.e., eye or hand). The effects may be decreased by reducing the transmission of vibration to the eye or to the hand or by making the task less susceptible to disturbance (e.g., increasing the size of a display or reducing the sensitivity of a control). Often, the effects of vibration on vision and manual control can be much reduced by redesign of the task.

### 3.2.1 Vision

Reading a newspaper in a moving vehicle may be difficult because the paper is moving, the eye is moving, or both the paper and the eye are moving. There are many variables which affect visual performance in these conditions: it is not possible to represent adequately the effects of vibration on vision without considering the effects of these variables.

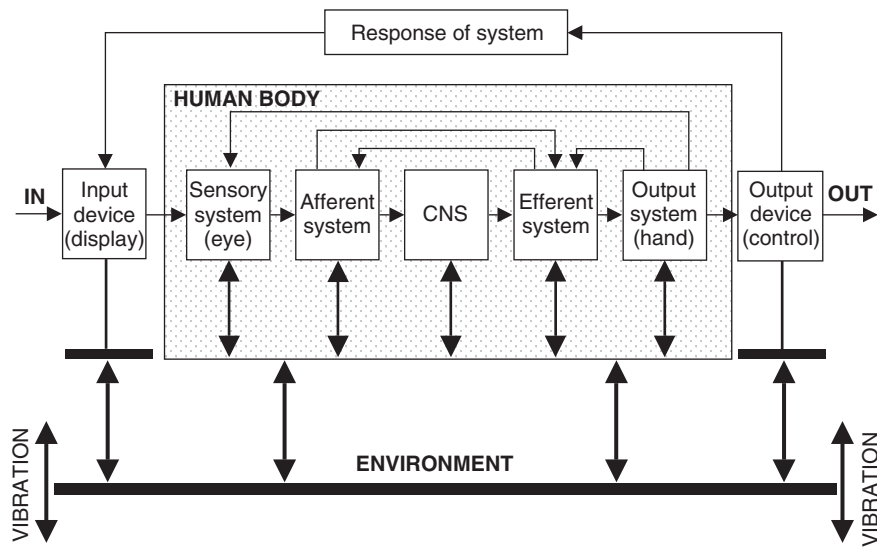
***Stationary Observer*** When a stationary observer views a moving display, the eye may be able to track the position of the display using *pursuit eye movements*. This closed-loop reflex will give smooth pursuit movements of the eye and clear vision if the display is moving at frequencies less than about 1 Hz and with a low velocity. At slightly higher frequencies of oscillation, the precise value depending on the predictability of the motion waveform, the eye will make *saccadic* eye movements to redirect the eye with small jumps. At frequencies greater than about 3 Hz, the eye will best be directed to one extreme of the oscillation and attempt to view the image as it is temporarily stationary


**Figure 5**  Information flow in a simple system and the areas where vibration may affect human activities.

while reversing the direction of movement (i.e., at the 'nodes' of the motion).

In some conditions, the absolute threshold for the visual detection of the vibration of an object occurs when the peak-to-peak oscillatory motion gives an angular displacement at the eye of approximately 1 min of arc. The acceleration required to achieve this threshold is very low at low frequencies but increases in proportion to the square of the frequency to become very high at high frequencies. When the vibration displacement is greater than the visual detection threshold, there will be perceptible blur if the vibration frequency is greater than about 3 Hz. The effects of vibration on visual performance (e.g., effects on reading speed and reading accuracy) may then be estimated from the maximum time that the image spends over some small area of the retina (e.g., the period of time spent near the nodes of the motion with sinusoidal vibration). For sinusoidal vibration this time decreases (and so reading errors increase) in linear proportion to the frequency of vibration and in proportion to the square root of the displacement of vibration (O'Hanlon and Griffin, 1971). With dual-axis vibration (e.g., combined vertical and lateral vibration of a display) this time is greatly reduced and reading performance drops greatly (Meddick and Griffin, 1976). With narrow-band random vibration there is a greater probability of low image velocity than with sinusoidal vibration of the same magnitude and predominant frequency, so reading performance tends to be less affected by random vibration than sinusoidal vibration (Moseley et al., 1982). Display vibration reduces the ability to see fine detail in displays while having little effect on the clarity of larger forms.

***Vibrating Observer***  If an observer is sitting or standing on a vibrating surface, the effects of vibration depend on the extent to which the vibration is transmitted to the eye. The motion of the head is highly dependent on body posture but is likely to occur in translational axes (i.e., in the *x*-, *y*-, and *z*-axes) and in rotational axes (i.e., in the roll, pitch, and yaw axes). Often, the predominant head motions affecting vision are in the vertical and pitch axes of the head. The dynamic response of the body may result in greatest head acceleration in these axes at frequencies around 5 Hz, but vibration at higher and lower frequencies can also have large effects on vision.

The pitch motion of the head is well compensated by the *vestibulo-ocular reflex*, which serves to help stabilize the line of sight of the eyes at frequencies less than about 10 Hz (e.g., Benson and Barnes, 1978). So, although there is often pitch oscillation of the head at 5 Hz, there is less pitch oscillation of the eyes at this frequency. Pitch oscillation of the head, therefore, has a less than expected effect on vision—unless the display is attached to the head, as with a helmet-mounted display (see Wells and Griffin, 1984).

The effects on vision of translational oscillation of the head depend on viewing distance: the effects are greatest when close to a display. As the viewing distance increases, the retinal image motions produced by translational displacements of the head decrease until, when viewing an object at infinite distance, there is no retinal image motion produced by translational head displacement (Griffin, 1976).

For a vibrating observer there may be little difficulty with low-frequency pitch head motions when viewing a fixed display and no difficulty with translational head motions when viewing a distant display. The greatest problems for a vibrating observer occur with pitch head motion when the display is attached to the head and with translational head motion when viewing near displays. Additionally, there may be resonances of the eye within the head, but these are highly variable between individuals and often occur at high frequencies

(e.g., 30 Hz and greater) and it is often possible to attenuate the vibration entering the body at these high frequencies.

***Observer and Display Vibrating*** When an observer and a display oscillate together, in phase, at low frequencies, the retinal image motions (and decrements in visual performance) are less than when either the observer or the display oscillates separately (Moseley and Griffin, 1986b). However, the advantage is lost as the vibration frequency increases because there is increasing phase difference between the oscillation of the head and the oscillation of the display. At frequencies around 5 Hz the phase lags between seat motion and head motion may be $90°$ or more (depending on seating conditions) and sufficient to eliminate any advantage of moving the seat and the display together. Figure 6 shows an example of how the time taken to read information on a screen is affected for the three viewing conditions (display vibration with a stationary observer, vibrating observer with stationary display, both observer and display vibrating) with sinusoidal vibration in the frequency range 0.5 to 5 Hz.

***Other Variables*** Some common situations in which vibration affects vision do not fall into one of the three categories in Figure 6. For example, when reading a newspaper on a train the motion of the arms may result in the motion of the paper being different in magnitude and phase from the motions of both the seat and the head of the observer. The dominant axis of motion of the newspaper may be different from the dominant axis of motion of the person (Griffin and Hayward, 1994).

Increasing the size of detail in a display will often greatly reduce adverse effects of vibration on vision

(Lewis and Griffin, 1979). In one experiment a 75% reduction in reading errors was achieved with only a 25% increase in the size of Landolt C targets (O'Hanlon and Griffin, 1971). Increasing the spacing between rows of letters and choosing appropriate character fonts can also be beneficial. The contrast of the display or other reading material also has an effect, but maximum performance may not occur with maximum contrast. The influence of such factors is summarized in a design guide for visual displays to be used in vibration environments (Moseley and Griffin, 1986a)

Optical devices may increase or decrease the effects of vibration on vision. Simple optical magnification of a vibrating object will increase both the apparent size of the object and the apparent magnitude of the vibration. Sometimes this will be beneficial if the benefits of increasing the size of the detail more than offset the effects of increased magnitude of vibration. The effect is similar to reducing the viewing distance, which can be beneficial for stationary observers viewing vibrating displays. If the observer is vibrating, the use of binoculars (and other magnifying devices) can be detrimental if the vibration of the device (e.g., rotation in the hand holding the binoculars) causes such an increase in the image movement that it is not sufficiently compensated by the increase in image size. The use of binoculars and telescopes in moving vehicles becomes difficult for these reasons.

### 3.2.2 Manual Control

Simple and complex manual control tasks can also be impeded by vibration. Studies of the effects of whole-body vibration on the performance of hand tracking tasks have been reviewed elsewhere (e.g., McLeod and Griffin, 1989). The characteristics of the task and the characteristics of the vibration combine to determine effects of vibration on activities: a given vibration may greatly affect the performance of one task but have little effect on the performance of another task.

***Effects Produced by Vibration*** The most obvious consequence of vibration on a continuous manual control task is the direct mechanical jostling of the hand causing unwanted movement of the control. This is sometimes called *breakthrough* or *feedthrough* or *vibration-correlated error*. The inadvertent movement of a pencil caused by "jostling" while writing in a vehicle is a form of *vibration-correlated error*. In a simple tracking task, where the operator is required to follow movements of a target, some of the error will also be correlated with the target movements. This is called *input-correlated error* and often mainly reflects the inability of an operator to follow the target without delays inherent in visual, cognitive, and motor activity. The part of the tracking error which is not correlated with either the vibration or the tracking task is called the 'remnant'. This includes operator-generated *noise* and any source of non-linearity: drawing a freehand straight line does not result in a perfect straight line even in the absence of environmental vibration. The effects of vibration on vision can result in increased remnant with some tracking tasks and some studies show

**Figure 6** Average times taken to read information on a display for (i) stationary observers reading from a vibrating display, (ii) vibrating observers reading from a stationary display, and (iii) vibration observers reading from a vibrating display with observer and display vibrating in phase. Data obtained with sinusoidal vertical vibration at 2.0m s$^{-2}$ r.m.s. (from Moseley and Griffin, 1986b).

**Figure 7** Linear model of a pursuit manual control system showing how tracking errors may be caused by the vibration (vibration-correlated error), the task (input-correlated error), or some other cause (remnant).

that vibration, usually at frequencies greater than about 20 Hz, interferes with neuromuscular processes, which may be expected to result in increased remnant. The causes of the three components of the tracking error are shown in the model presented as Figure 7.

***Effects of Task Variables*** The gain (i.e., sensitivity) of a control determines the control output corresponding to a given force, or displacement, applied to the control by the operator. The optimum gain in static conditions (high enough to not cause fatigue but low enough to prevent inadvertent movement) is likely to be greater than the optimum gain during exposure to vibration where inadvertent movement is more likely (Lewis and Griffin, 1977). First-order and second-order control tasks (i.e., rate and acceleration control tasks) are more difficult than zero-order tasks (i.e., displacement control tasks) and so tend to give more errors. However, there may sometimes be advantages with such controls that are less affected by vibration breakthrough at higher vibration frequencies.

In static conditions, isometric controls (that respond to force without movement) tend to result in better tracking performance than isotonic controls (that respond to movement but require the application of no force). However, several studies show that isometric controls may suffer more from the effects of vibration (e.g., Allen et al., 1973; Levison and Harrah, 1977). The relative merits of the two types of control and the optimum characteristics of a spring-centered control will depend on control gain and control order.

The results of studies investigating the influence of the position of a control appear consistent with differences being dependent on the transmission of vibration to the hand in different positions (e.g., Shoenberger and Wilburn, 1973). Torle (1965) showed that the provision of an armrest could substantially reduce the effects of vibration on the performance of a task with a side-arm controller. The shape and orientation of controls may also be expected to affect performance—either by modifying the amount of

vibration breakthrough or by altering the proprioceptive feedback to the operator.

Vibration may affect the performance of tracking tasks by reducing the visual performance of the operator. Wilson (1974) and McLeod and Griffin (1990) have shown that collimating a display by means of a lens so that the display appears to be at infinity can reduce, or even eliminate, errors with some tasks. It is possible that visual disruption has played a significant part in the performance decrements reported in other experimental studies of the effects of vibration on manual control.

Some simple tasks can be so easy that they are immune to disruption by vibration. At the other extreme, a task may be so difficult that any additional difficulty caused by vibration may be insignificant. Tasks with moderate ranges of difficulty in static conditions tend to be most disrupted by whole-body vibration.

***Effects of Vibration Variables*** The vibration transmissibility of the body is approximately linear (i.e., doubling the magnitude of vibration at the seat may be expected to approximately double the magnitude of vibration at the head or at the hand). Vibration-correlated error may therefore increase in approximately linear proportion to vibration magnitude.

There is no simple relation between the frequency of vibration and its effects on control performance. The effects of frequency depend on the control order (that varies between tasks) and the biodynamic responses of the body (that varies with posture and between operators). With zero-order tasks and the same magnitude of acceleration at each frequency, the effects of vertical seat vibration may be greatest in the range 3 to 8 Hz since transmissibility to the shoulders is greatest in this range (see McLeod and Griffin, 1989). With horizontal whole-body vibration (i.e., in the $x$- and $y$-axes of the seated body) the greatest effects appear to occur at lower frequencies: around 2 Hz or below. Again, this corresponds to the frequencies at which there is greatest transmission of vibration to the shoulders. The axis of the control task most affected by vibration may not be the same axis as that in which most vibration occurs at

the seat. Often, fore-and-aft movements of the control (which generally correspond to vertical movements on a display) are most affected by vertical whole-body vibration. Few controls are sensitive to vertical hand movements and these have rarely been studied.

Multiple-frequency vibration causes more disruption to manual control performance than the presentation of any one of the constituent single frequencies alone. Similarly, the effects of multiple-axis vibration are greater than the effects of any single axis vibration.

The impression that prolonged exposure to vibration causes fatigue gave rise to the *fatigue-decreased proficiency* boundary in International Standard 2631, first published in 1974 (ISO, 1974, 1985, p. 4). This standard proposed a complex time-dependent magnitude of vibration which is said to be "a limit beyond which exposure to vibration can be regarded as carrying a significant risk of impaired working efficiency in many kinds of tasks, particularly those in which time-dependent effects ("fatigue") are known to worsen performance as, for example, in vehicle driving." Reviews of experimental studies show time-dependent effects of performance in only a few cases, with performance sometimes improving with time. It can be concluded that the evidence supporting the old ISO 2631 fatigue-decreased proficiency boundary is weak or nonexistent. There are no data justifying a time-dependent limit for the effects of vibration on performance with the complexity included in International Standard 2631 (ISO, 1974, 1985). Any duration-dependent effects of vibration may be influenced by complex central factors including motivation, arousal, and similar concepts that depend on the form of the task: they may not lend themselves to satisfactory representation by a single time-dependent limit in an international standard. The most common and most easily understood 'direct' effects of vibration on vision and manual control are not intrinsically dependent on the duration of vibration exposure.

***Other Variables***   Repeated exposure to vibration may allow subjects to develop techniques for minimizing vibration effects by, for example, adjusting body posture to reduce the transmission of vibration to the head or the hand or by learning how to recognize images blurred by vibration. Results of experiments performed in one experimental session of vibration exposure may not necessarily apply to situations where operators have an opportunity to learn techniques to ameliorate the effects of vibration.

There have been few investigations of the effects of vibration on common everyday tasks. Corbridge and Griffin (1991) found that the effects of vertical whole-body vibration on spilling liquid from a hand-held cup were greatest close to 4 Hz. They also found that the effects of vibration on writing speed and subjective estimates of writing difficulty were most affected by vertical vibration in the range 4 to 8 Hz. Although 4 Hz was a sensitive frequency for both the drinking task and the writing task, the dependence on frequency of the effects of vibration were different for the two activities.

Whole-body vibration can cause a warbling of speech due to fluctuations in the airflow through the larynx.

Greatest effects may occur with vertical vibration in the range 5–20 Hz, but they are not usually sufficient to reduce greatly the intelligibility of speech (e.g., Nixon and Sommer, 1963). Some studies suggest that exposure to vibration may contribute to noise-induced hearing loss, but further study is required to allow a full interpretation of these data.

### 3.2.3   Cognitive Tasks

To be useful, studies of cognitive effects of vibration must be able to show that any changes associated with exposure to vibration were not caused by vibration affecting input processes (e.g., vision) or output processes (e.g., hand control). Only a few investigators have addressed possible cognitive effects of vibration with care and considered such problems. For example, Shoenberger (1974) found that with the Sternberg memory-reaction-time task the time taken for subjects to recall letters presented on a display depended on the angular size of the letters. He was able to conclude that performance was degraded by visual effects of vibration and not by cognitive effects of vibration. In most other studies there has been little attempt to develop hypotheses to explain any significant effects of vibration in terms of the component processes involved in cognitive processing.

Simple cognitive tasks (e.g., simple reaction time) appear to be unaffected by vibration, other than by changes in arousal or motivation or by direct effects on input and output processes. This may also be true for some complex cognitive tasks. However, the scarcity and diversity of experimental studies allow the possibility of real and significant cognitive effects of vibration (see Sherwood and Griffin, 1990, 1992). Vibration may influence 'fatigue', but there is no scientific foundation for the *fatigue-decreased proficiency limit* offered in the former International Standard 2631 (ISO, 1974, 1985).

### 3.3   Health Effects

Epidemiological studies have reported disorders among persons exposed to vibration from occupational, sport, and leisure activities [see Dupuis and Zerlett, 1986; Griffin, 1990; National Institute for Occupational Safety and Health (NIOSH), 1997; Bovenzi and Hulshof, 1998; Bovenzi, 2009]. The studies do not all agree on either the type or the extent of disorders and rarely have the findings been related to measurements of the vibration exposures. However, the incidence of some disorders of the back (back pain, displacement of intervertebral discs, degeneration of spinal vertebrae, osteoarthritis, etc.) appears to be greater in some groups of vehicle operators, and it is thought that this is sometimes associated with their vibration exposure. There may be several alternative causes of an increase in disorders of the back among persons exposed to vibration (e.g., poor sitting postures, heavy lifting). It is not always possible to conclude confidently that a back disorder in a person occupationally exposed to whole-body vibration is solely, or primarily, caused by vibration.

Other disorders that have been claimed to be due to occupational exposures to whole-body vibration include abdominal pain, digestive disorders, urinary

frequency, prostatitis, hemorrhoids, balance and visual disorders, headaches, and sleeplessness. Further research is required to confirm whether these signs and symptoms are causally related to exposure to vibration.

### 3.3.1 Vibration Evaluation

Epidemiological data alone are not sufficient to define how to evaluate whole-body vibration so as to predict the relative risks to health from the different types of vibration exposure. A consideration of such data in combination with an understanding of biodynamic responses and subjective responses is used to provide current guidance. The manner in which the health effects of oscillatory motions depend upon the frequency, direction, and duration of motion is currently assumed to be similar to that for vibration discomfort (see Section 3.1). However, it is assumed that the *total exposure*, rather than the *average exposure*, is important and so a *dose measure* is used.

British Standard 6841 (BSI, 1987) and International Standard 2631-1 (ISO, 1997) can be interpreted as providing similar guidance, but there is more than one method within ISO 2631-1 and the alternative methods can yield different conclusions (Griffin, 1998).

### 3.3.2 British Standard 6841

British Standard 6841 (BSI, 1987) defines an *action level* for vertical vibration based on *vibration dose values*. The vibration dose value uses a 'fourth-power' time-dependency to accumulate vibration severity over the exposure period from the shortest possible shock to a full day of vibration:

$$\text{Vibration dose value} = \left[ \int_{t=0}^{t=T} a^4(t) dt \right]^{1/4} \qquad (1)$$

where $a(t)$ is the frequency-weighted acceleration. If the exposure duration ($t$, seconds) and the frequency-weighted r.m.s. acceleration ($a_{rms}$, m s$^{-2}$ r.m.s.) are known for conditions in which the vibration characteristics are statistically stationary, it can be useful to calculate the *estimated vibration dose value* (eVDV):

$$\text{eVDV} = 1.4 a_{rms} t^{1/4} \qquad (2)$$

The eVDV is not applicable to transients, shocks, or repeated shock motions in which the crest factor (peak value divided by the r.m.s. value) is high.

No precise limit can be offered to prevent disorders caused by whole-body vibration, but British Standard 6841 (BSI, 1987, p. 18) offers the following guidance: "High vibration dose values will cause severe discomfort, pain and injury. Vibration dose values also indicate, in a general way, the severity of the vibration exposures which caused them. However there is currently no consensus of opinion on the precise relation between vibration dose values and the risk of injury. It is known that vibration magnitudes and durations which produce vibration dose values in the region of 15 m s$^{-1.75}$ will usually cause severe discomfort. It is reasonable to assume that increased exposure to vibration will be accompanied by increased risk of injury." An action level might be set higher or lower than 15 m s$^{-1.75}$. Figure 8 shows this action level for exposure durations from 1 s to one day.

### 3.3.3 International Standard 2631

International Standard 2631 (ISO, 1997, p. 22) offers two different methods of evaluating vibration severity with respect to health effects, and for both methods there are two boundaries. When evaluating vibration using the vibration dose value, it is suggested that below a boundary corresponding to vibration dose value of 8.5 m s$^{-1.75}$ "health risks have not been objectively observed," between 8.5 and 17 m s$^{-1.75}$ "caution with respect to health risks is indicated," and above 17 m s$^{-1.75}$ "health risks are likely." The two boundaries define a *VDV health guidance caution zone*. The alternative method of evaluation in ISO 2631 (ISO, 1997) uses a time dependency in which the acceptable vibration does not vary with duration between 1 and 10 min and then decreases in inverse proportion to the square root of duration from 10 min to 24 h. This method suggests an *r.m.s. health guidance caution zone*, but the method is not fully defined in the text, it allows very high accelerations at some durations, it conflicts with the vibration dose value method, and it may not be applicable to exposure durations less than 1 min (Figure 8).

When the possibility of severe exposures to vibration or shock can be foreseen, it is appropriate to consider the fitness of the exposed persons, warn of the risks and train on ways of minimizing risks, minimize the duration of exposure to vibration, and minimize the magnitude of exposure (by suitable selection and maintenance of machinery or driving routes and the design of antivibration devices). Suitable health surveillance and monitoring of vibration-exposed persons may also be appropriate.

### 3.3.4 EU Machinery Safety Directive

The Machinery Safety Directive of the European Community (2006/42/EC, paragraph 1.5.9) states: "Machinery must be designed and constructed in such a way that risks resulting from vibrations produced by the machinery are reduced to the lowest level, taking account of technical progress and the availability of means of reducing vibration, in particular at source" (European Parliament and the Council of the European Union, 2006). The instruction handbooks for machinery causing whole-body vibration must specify the frequency-weighted acceleration if this exceeds a frequency-weighted acceleration of 0.5 m s$^{-2}$ r.m.s. The relevance of any such value will depend on the test conditions to be specified in other standards. Many work vehicles exceed this value at some stage during an operation or journey. Standardized procedures for testing work vehicles are being prepared; the values currently quoted by manufacturers may not always be representative of the operating conditions in the work for which the machinery is used. The Machinery Safety Directive
**Figure 8** Comparison between health guidance caution zones for whole-body vibration in ISO 2631-1 (ISO, 1997) (3 to 6 ms$^{-2}$ r.m.s.; 8.5 to 17m s$^{-1.75}$), 15m s$^{-1.75}$ action level implied in BS 6841 (BSI, 1987), the r.m.s. and eVDV exposure limit values and exposure action values for whole-body vibration in the EU Physical Agents (Vibration) Directive.

affects all manufacturers wishing to sell machines in the EU and therefore has a worldwide impact.

### 3.3.5 EU Physical Agents Directive (2002)

The Parliament and Commission of the European Community have defined *minimum health and safety requirements* for the exposure of workers to the risks arising from vibration (European Parliament and the Council of the European Union, 2002). For whole-body vibration, the Directive defines an 8-h equivalent *exposure action value* of 0.5 m s$^{-2}$ r.m.s. (or a vibration dose value of 9.1 m s$^{-1.75}$) and an 8-h equivalent *exposure limit value* of 1.15 ms$^{-2}$ r.m.s. (or a vibration dose value of 21 m s$^{-1.75}$).

The Directive says that workers shall not be exposed above the 'exposure limit value'. If the 'exposure action value' is exceeded, the employer shall establish and implement a program of technical and/or organizational measures intended to reduce to a minimum exposure to mechanical vibration and the attendant risks. The Directive says workers exposed to vibration in excess of the exposure action values shall be entitled to appropriate health surveillance. Health surveillance is also required if there is any reason to suspect that workers may be injured by the vibration even if the exposure action value is not exceeded.

The probability of injury arising from occupational exposures to whole-body vibration at the exposure action value and the exposure limit value cannot be estimated because epidemiological studies have not yet produced dose–response relationships. However, it seems clear that the Directive does not define *safe exposures* to whole-body vibration since the r.m.s.

values are associated with extraordinarily high magnitudes of vibration (and shock) when the exposures are short: these exposures may be assumed to be hazardous (see Figure 8; Griffin, 2004). The vibration dose value procedure suggests more reasonable vibration magnitudes for short-duration exposures.

### 3.4 Disturbance in Buildings

Acceptable magnitudes of vibration in buildings are generally close to, or below, vibration perception thresholds (Morioka and Griffin, 2008). The effects of vibration in buildings are assumed to depend on the use of the building in addition to the vibration frequency, the vibration direction and the vibration duration. International Standard 2631-2 (ISO, 2003) provides some information on the measurement and evaluation of building vibration, but limited practical guidance. British Standard 6472-1 (BSI, 2008) offers guidance on the measurement, the evaluation, and the assessment of vibration in buildings, and BS 6472-2 (BSI, 2008) defines a method used for assessing the vibration of buildings caused by blasting. Using the guidance contained in BS 6472-1 (BSI, 2008) it is possible to predict the acceptability of vibration in different types of building by reference to a simple table of vibration dose values [see Table 5 and British Standard 6472-1 (BSI, 2008)]. The vibration dose values in Table 5 are applicable irrespective of whether the vibration occurs as a continuous vibration, intermittent vibration, or repeated shocks.

### 3.5 Biodynamics

The human body is a complex mechanical system that does not, in general, respond to vibration in the same

**Table 5 Vibration Dose Value Ranges Expected to Result in Various Degrees of Adverse Comment in Residential Buildings**

| Place | Low Probability Of Adverse Comment (ms$^{-1.75}$) | Adverse Comment Possible (ms$^{-1.75}$) | Adverse Comment Probable (ms$^{-1.75}$) |
|---|---|---|---|
| Residential buildings 16-h day | 0.2–0.4 | 0.4–0.8 | 0.8–1.6 |
| Residential buildings 8-h night | 0.1–0.2 | 0.2–0.4 | 0.4–0.8 |

*Note:* Based on British Standard 6472-1 (BSI, 2008). For offices and workshops, multiplying factors of 2 and 4, respectively, can be applied to the vibration dose value ranges for a 16-h day.

manner as a rigid mass: relative motions between the body parts vary with the frequency and the direction of the applied vibration. Although there are resonances in the body, it is over-simplistic to summarize the dynamic responses of the body by merely mentioning one or two resonance frequencies. The biodynamics of the body affect human responses to vibration, but the discomfort, the interference with activities, and the health effects of vibration cannot be well predicted solely by considering the body as a mechanical system.

### 3.5.1 Transmissibility of Human Body

The extent to which the vibration at the input to the body (e.g., the vertical vibration at a seat) is transmitted to a part of the body (e.g., vertical vibration at the head or the hand) is described by the transmissibility. At low frequencies of oscillation (e.g., less than about 1 Hz), the oscillations of the seat and the body are very similar and so the transmissibility is approximately 1.0. With increasing frequency of oscillation the motions of the body increase above that measured at the seat; the ratio of the motion of the body to the motion of the seat will reach a peak at one or more frequencies (i.e., resonance frequencies). At high frequencies the body motion will be less than that at the seat.

The resonance frequencies and the transmissibilities at resonance vary according to where the vibration is measured on the body and the posture of the body. For seated persons, there may be resonances to the head and the hand at frequencies in the range 4 to 12 Hz when exposed to vertical vibration, at frequencies less than 4 Hz when exposed to $x$-axis (i.e., fore-and-aft) vibration, and less than 2 Hz when exposed to $y$-axis (i.e., lateral) vibration (see Paddan and Griffin, 1988a,b). A seat back can greatly increase the transmission of fore-and-aft seat vibration to the head and upper-body of seated people, and bending of the legs can greatly affect the transmission of vertical vibration to the heads of standing persons.

### 3.5.2 Mechanical Impedance of Human Body

Mechanical impedance reflects the relation between the driving force at the input to the body and the resultant movement of the body. If the human body were rigid, the ratio of force to acceleration applied to the body would be constant and indicate the mass of the body. Because the human body is not rigid, the ratio of force to acceleration is only close to the body mass at very low frequencies (less than about 2 Hz with vertical vibration; less than about 1 Hz with horizontal vibration).

Measures of mechanical impedance usually show a principal resonance for the vertical vibration of seated people at about 5 Hz, and sometimes a second resonance in the range 7 to 12 Hz (Fairley and Griffin, 1989; Matsumoto and Griffin, 2000, 2001; Nawayseh and Griffin, 2003). Unlike some of the resonances affecting the transmissibility of the body, these resonances are only influenced by movement of large masses close to the input of vibration to the body. The large difference in impedance between that of a rigid mass and that of the human body means that the body cannot usually be represented by a rigid mass when measuring the vibration transmitted through seats.

### 3.5.3 Biodynamic Models

Various mathematical models of the responses of the body to vibration have been developed. A simple model with one or two degrees-of-freedom can provide an adequate representation of the vertical mechanical impedance of the body (e.g., Fairley and Griffin, 1989; Wei and Griffin, 1998a) and be used to predict the transmissibility of seats (Wei and Griffin, 1998b) or construct an anthropodynamic dummy for seat testing (Lewis and Griffin, 2002). Compared with mechanical impedance, the transmissibility of the body is affected by many more variables and so requires a more complex model reflecting the posture of the body and the translation and rotation associated with the various modes of vibration (Matsumoto and Griffin, 2001).

### 3.6 Protection from Whole-Body Vibration

Wherever possible, vibration should be reduced at the source. This may involve reducing the undulations of the terrain, or reducing the speed of travel of vehicles, or improving the balance of rotating parts. Methods of reducing the transmission of vibration to operators require an understanding of the characteristics of the vibration environment and the route for the transmission of vibration to the body. For example, the magnitude of vibration often varies with location: lower magnitudes will be experienced in some areas adjacent to machinery or in different parts of vehicles.

### 3.6.1 Seating Dynamics

Most seats exhibit a resonance at low frequencies that results in higher magnitudes of vertical vibration occurring on the seat than on the floor! At high frequencies there is usually attenuation of vibration. The resonance frequencies of common seats are usually in the region of 4 Hz (see Figure 9). The amplification at resonance is partially determined by the 'damping' in the seat. Increases in the damping of a seat cushion tend to reduce the amplification at resonance but increase the transmission of vibration at higher frequencies. The
**Figure 9** Comparison of vertical transmissibilities and SEAT values for 10 alternative cushions of passenger railway seats (data from Corbridge et al., 1989).

variations in transmissibility between seats are sufficient to result in significant differences in the vibration experienced by people supported by different seats.

A simple numerical indication of the isolation efficiency of a seat for a specific application is provided by the *seat effective amplitude transmissibility* (SEAT) (Griffin, 1990). A SEAT value greater than 100% indicates that, overall, the vibration on the seat is 'worse' than the vibration on the floor beneath the seat:

$$SEAT(\%) = \frac{\text{ride comfort seat}}{\text{ride comfort floor}} \times 100$$

Values below 100% indicate that the seat has provided some useful attenuation. Seats should be designed to have the lowest SEAT value compatible with other constraints.

In practice, the SEAT value is a mathematical procedure for predicting the effect of a seat on ride comfort. The *ride comfort* that would result from sitting on the seat or on the floor can be predicted using the frequency weightings in the appropriate standard. The SEAT value may be calculated from the r.m.s. values or the vibration dose values of the frequency-weighted acceleration on the seat and the floor:

$$SEAT(\%) = \frac{\text{vibration dose value on seat}}{\text{vibration dose value on floor}} \times 100$$

The SEAT value is a characteristic of the vibration input and not merely a description of the dynamics of the seat: different values are obtained with the same seat in different vehicles. The SEAT value indicates the suitability of a seat for a particular type of vibration.

A separate suspension mechanism is provided beneath the seat pan in *suspension seats*. These seats,

used in some off-road vehicles, trucks, and coaches, have low resonance frequencies (often less than about 2 Hz) and so can attenuate vibration at frequencies much greater than 2 Hz. The transmissibilities of these seats are usually determined by the seat manufacturer, but their isolation efficiencies vary with operating conditions.

## 4 MOTION SICKNESS

Motion sickness is not an illness but a normal response to motion that is experienced by many fit and healthy people. A variety of different motions can cause sickness and reduce the comfort, impede the activities, and degrade the well-being of both those directly affected and those associated with the motion sick. Although vomiting can be the most inconvenient consequence, other effects (e.g., yawning, cold sweating, nausea, stomach awareness, dry mouth, increased salivation, headaches, bodily warmth, dizziness, and drowsiness) can also be unpleasant. In some cases the symptoms can be so severe as to result in reduced motivation to survive difficult situations.

### 4.1 Causes of Motion Sickness

Motion sickness can be caused by many different movements of the body (e.g., translational and rotational oscillation, constant speed rotation about an off-vertical axis, Coriolis stimulation), movements of the visual scene, and various other stimuli producing sensations associated with movement of the body (see Table 6 and Griffin, 1991). Motion sickness is neither explained nor predicted solely by the physical characteristics of the motion, although some motions can reliably be predicted as more nauseogenic than others.

**Table 6 Examples of Environments, Activities, and Devices that Can Cause Symptoms of Motion Sickness**

| | |
|---|---|
| Boats | Camel rides |
| Ships | Elephant rides |
| Submarines | |
| Hydrofoils | Vehicle simulators |
| Hovercraft | |
| Swimming | Fairground devices |
| Fixed-wing aircraft | Cinerama |
| Helicopters | Inverting or distorting spectacles |
| Spacecraft | Microfiche readers |
| | Head-coupled visual displays |
| Cars | |
| Coaches | Rotation about off-vertical axis |
| Buses | Coriolis stimulation |
| Trains | Low-frequency translational oscillation |
| Tanks | |

Motions of the body may be detected by three basic sensory systems: the vestibular system, the visual system, and the somatosensory system. The vestibular system is located in the inner ear and comprises the semicircular canals, which respond to the rotation of the head, and the otoliths, which respond to translational forces (either translational acceleration or rotation of the head relative to an acceleration field, such as the force of gravity). The eyes may detect relative motion between the head and the environment, caused by either head movements (in translation or rotation) or movements of the environment or a combination of the movements of the head and the environment. The somatosensory systems respond to force and displacement of parts of the body and give rise to sensations of body movement, or force.

It is assumed that in 'normal' environments the movements of the body are detected by all three sensory systems and that this leads to an unambiguous indication of the movements of the body in space. In some other environments the three sensory systems may give signals corresponding to different motions (or motions that are not realistic) and lead to some form of conflict. This leads to the idea of a *sensory conflict theory* of motion sickness in which sickness occurs when the sensory systems disagree on the motions which are occurring. However, this implies some absolute significance to sensory information, whereas the 'meaning' of the information is probably learned. This led to the *sensory rearrangement theory* of motion sickness that states: all situations which provoke motion sickness are characterized by a condition of sensory rearrangement in which the motion signals transmitted by the eyes, the vestibular system and the non-vestibular proprioceptors are at variance either with one another or with what is expected from previous experience (Reason, 1970, 1978). Reason and Brand (1975) suggest that the conflict may be sufficiently

considered in two categories: intermodality (between vision and the vestibular receptors) and intramodality (between the semicircular canals and the otoliths within the vestibular system). For both categories it is possible to identify three types of situations in which conflict can occur (see Table 7). The theory implies that all situations which provoke motion sickness can be fitted into one of the six conditions shown in Table 7 (see Griffin, 1990).

There is evidence that the average susceptibility to sickness among males is less than that among females, and susceptibility decreases with increased age among both males and females (Lawther and Griffin, 1988a; Turner and Griffin, 1999). However, there are larger individual differences within any group of either gender at any age: some people are easily made ill by motions that can be endured indefinitely by others. The reasons for these differences are not properly understood.

## 4.2 Sickness Caused by Oscillatory Motion

Motion sickness is not caused by oscillation (however violent) at frequencies much greater than about 1 Hz: the phenomenon arises from motions at the low frequencies associated with normal postural control of the body. Various experimental investigations have explored the extent to which vertical oscillation causes sickness at different frequencies. These studies have allowed the formulation of a frequency weighting, $W_f$ (see Figure 4), and the definition of a *motion sickness dose value*, MSDV. The frequency weighting $W_f$ reflects greatest sensitivity to acceleration in the range 0.125 to 0.25 Hz, with a rapid reduction in sensitivity at higher frequencies. The motion sickness dose value predicts the probability of sickness from knowledge of the frequency and magnitude of vertical oscillation (see Lawther and Griffin, 1987; British Standard 6841, 1987; International Standard 2631-1, 1997):

$$\text{Motion sickness dose value} = a_{rms}t^{1/2}$$

where $a_{rms}$ is the r.m.s. value of the frequency-weighted acceleration (m s$^{-2}$ r.m.s.) and $t$ is the exposure period (seconds). The percentage of unadapted adults who are expected to vomit is given by 1/3 MSDV. (These relationships have been derived from exposures in which up to 70% of persons vomited during exposures lasting between 20 min and 6 h).

The motion sickness dose value has been used for the prediction of sickness on various marine craft (ships, hovercraft, and hydrofoil) in which vertical oscillation has been shown to be a prime cause of sickness (Lawther and Griffin, 1988b). Vertical oscillation is not the principal cause of sickness in many road vehicles (Turner and Griffin, 1999; Griffin and Newman, 2004) and some other environments: the above expression should not be assumed to be applicable to the prediction of sickness in all environments.

## 5 HAND-TRANSMITTED VIBRATION

Prolonged and regular exposure of the fingers or the hands to vibration or repeated shock can give rise to

**Table 7  Type of Motion Cue Mismatch Produced by Various Provocative Stimuli**

| | Category of Motion Cue Mismatch | |
|---|---|---|
| | Visual (A) / Vestibular (B) | Canal (A) / Otolith (B) |
| TYPE 1<br>  A and B simultaneously give contradictory or uncorrelated information | Watching waves from a ship | Making head movements while rotating (Coriolis or cross-coupled stimulation) |
| | Use of binoculars in a moving vehicle | Making head movements in an abnormal environment which may be constant (e.g., hyper- or hypogravity) or fluctuating (e.g., linear oscillation) |
| | Making head movements when vision is distorted by an optical device | Space sickness |
| | ''Pseudo-Coriolis'' stimulation | Vestibular disorders (e.g., Ménière's disease, acute labyrinthitis, trauma labyrinthectomy) |
| TYPE IIa<br>  A signals in absence of expected B signal | Cinerama sickness | Positional alcohol nystagmus |
| | Simulator sickness | Caloric stimulation of semicircular canals |
| | ''Haunted swing'' | Vestibular disorders (e.g., pressure vertigo, cupulolithiasis) |
| | Circular vection | |
| TYPE IIb<br>  B signals in absence of expected A signals | Looking inside a moving vehicle without external visual reference (e.g., below deck in a boat) | Low-frequency ($<0.5$ Hz) translational oscillation |
| | Reading in a moving vehicle | Rotating linear acceleration vector (e.g., ''barbecue spit'' rotation, rotation about an off-vertical axis) |

*Source*: Adapted from Benson (1984).

various signs and symptoms of disorder. The precise extent and interrelation between the signs and symptoms are not fully understood, but five types of disorder may be identified (see Table 8).

The various disorders may be interconnected: more than one disorder can affect a person at the same time and it is possible that the presence of one disorder facilitates the appearance of another. The onset of each disorder is dependent on several variables, such as the vibration characteristics, the dynamic response of the fingers or hand, individual susceptibility to damage, and other aspects of the environment. The terms *vibration*

**Table 8  Five Types of Disorder Associated with Hand-Transmitted Vibration Exposures**

| Type | Disorder |
|---|---|
| Type A | Circulatory disorders |
| Type B | Bone and joint disorders |
| Type C | Neurological disorders |
| Type D | Muscle disorders |
| Type E | Other general disorders (e.g., central nervous system) |

*Source*: From Griffin (1990).
*Note*: Some combination of these disorders is sometimes referred to as the hand–arm vibration syndrome (HAVS).

*syndrome* and *hand–arm vibration syndrome* (HAVS) are sometimes used to refer to one or more of the effects listed in Table 8.

## 5.1  Sources of Hand-Transmitted Vibration

The vibration on tools varies greatly depending on tool design and method of use, so it is not possible to categorize individual tool types as *safe* or *dangerous*. However, Table 9 lists examples of tools and processes that are sometimes a cause for concern.

## 5.2  Effects of Hand-Transmitted Vibration

### 5.2.1  Vascular Disorders

The first published cases of the condition now most commonly known as *vibration-induced white finger* (VWF) are acknowledged to be those reported in Italy by Loriga in 1911. A few years later, cases were documented at limestone quarries in Indiana. Vibration-induced white finger has subsequently been reported to occur in many other widely varied occupations in which there are exposures of the fingers to vibration (see Taylor and Pelmear, 1975; Wasserman et al., 1982; Griffin, 1990).

***Signs and Symptoms***  Vibration-induced white finger (VWF), is characterized by intermittent whitening (i.e., blanching) of the fingers (Griffin and Bovenzi,

**Table 9  Examples of Tools and Processes Potentially Associated with Vibration Injuries**

| Type of Tool | Examples of Tool Type |
|---|---|
| Percussive metal-working tools | Riveting tools |
| | Caulking tools |
| | Chipping tools |
| | Chipping hammers |
| | Fettling tools |
| | Hammer drills |
| | Clinching and flanging tools |
| | Impact wrenches |
| | Swaging |
| | Needle guns |
| Grinders and other rotary tools | Pedestal grinders |
| | Hand-held grinders |
| | Hand-held sanders |
| | Hand-held polishers |
| | Flex-driven grinders/polishers |
| | Rotary burring tools |
| Percussive hammers and drills used in mining, demolition and road construction | Hammers |
| | Rock drills |
| | Road drills, etc. |
| Forest and garden machinery | Chain saws |
| | Antivibration chain saws |
| | Brush saws |
| | Mowers and shears |
| | Barking machines |
| Other processes and tools | Nut runners |
| | Shoe-pounding-up machines |
| | Concrete vibro-thickeners |
| | Concrete leveling vibrotables |
| | Motorcycle handle bars |

2002). The finger tips are usually the first to blanch, but the affected area may extend to all of one or more fingers with continued vibration exposure. Attacks of blanching are precipitated by cold and therefore usually occur in cold conditions or when handling cold objects. The blanching lasts until the fingers are rewarmed and vasodilation allows the return of the blood circulation.

Many years of vibration exposure often occur before the first attack of blanching is noticed. Affected persons often have other signs and symptoms, such as numbness and tingling. Cyanosis and, rarely, gangrene have also been reported. It is not yet clear to what extent these other signs and symptoms are causes of, caused by, or unrelated to attacks of white finger.

***Diagnosis***  There are other conditions that can cause similar signs and symptoms to those associated with VWF. Vibration-induced white finger cannot be assumed to be present merely because there are attacks of blanching. It will be necessary to exclude other known causes of similar symptoms (by medical examination) and also necessary to exclude so-called primary Raynaud's disease (also called *constitutional white finger*). This exclusion cannot yet be achieved with complete confidence, but if there is no family history of the symptoms, if the symptoms did not occur before the first significant exposure to vibration, and if the symptoms and signs are confined to areas in contact with the vibration (e.g., the fingers, not the ears), they will often be assumed to indicate vibration-induced white finger.

Diagnostic tests for vibration-induced white finger can be useful, but at present they are not infallible indicators of the disease. The measurement of finger systolic blood pressure following finger cooling and the measurement of finger rewarming times following cooling can be useful, but many others tests are in use (see Griffin and Bovenzi, 2002).

The severity of the effects of vibration is sometimes recorded by reference to the *stage* of the disorder. The staging of vibration-induced white finger is often based on verbal statements made by the affected person recalling an attack of finger blanching, but it may be influenced by evidence in photographs taken during an attack. In the Stockholm Workshop staging system, the staging is influenced by both the frequency of attacks of blanching and the areas of the digits affected by blanching (see Table 10).

A scoring system is used to record the areas of the digits affected by blanching (see Figure 10). The scores correspond to areas of blanching on the digits commencing with the thumb. On the fingers a score of 1 is given for blanching on the distal phalanx, a score of 2 for blanching on the middle phalanx, and a score of 3 for blanching on the proximal phalanx. On the thumbs the scores are 4 for the distal phalanx and 5 for the proximal phalanx. The blanching score may be based on statements from the affected person or on the visual observations of a designated observer (e.g., a nurse).

**Table 10  Stockholm Workshop Scale for Classification of Vibration-Induced White Finger**

| Stage | Grade | Description |
|---|---|---|
| 0 | — | No attacks |
| 1 | Mild | Occasional attacks affecting only the tips of one or more fingers |
| 2 | Moderate | Occasional attacks affecting distal and middle (rarely also proximal) phalanges of one or more fingers |
| 3 | Severe | Frequent attacks affecting all phalanges of most fingers |
| 4 | Very severe | As in stage 3, with trophic skin changes in the finger tips |

*Source*: From Gemne et al., (1987).
*Note*: If a person has stage 2 in two fingers of the left hand and stage 1 in a finger on the right hand, the condition may be reported as 2L(2)/1R(1). There is no defined means of reporting the condition of digits when this varies between digits on the same hand. The scoring system is more helpful when the extent of blanching is to be recorded.
**Figure 10** Method of scoring areas of digits affected by blanching (from Griffin, 1990). The blanching scores for the hands shown are $01300_{right}$, $01366_{left}$.

### 5.2.2 Neurological Disorders

Neurological effects of hand-transmitted vibration (e.g., numbness, tingling, elevated sensory thresholds for touch, vibration, temperature and pain, and reduced nerve conduction velocity) are considered to be separate effects of vibration and not merely symptoms of vibration-induced white finger (Griffin and Bovenzi, 2002). A method of reporting the extent of vibration-induced neurological effects of vibration has been proposed (see Table 11). This staging is not currently related to the results of any specific objective test: the *sensorineural stage* is a subjective impression of a physician based on the statements of the affected person or the results of any available clinical or scientific testing. Neurological disorders are sometimes identified by screening tests using measures of sensory function, such as the thresholds for feeling vibration, heat, or coldness on the fingers.

### 5.2.3 Muscular Effects

The research literature includes reports of muscle atrophy among users of vibrating tools. Workers exposed to hand-transmitted vibration sometimes report difficulty with their grip, including reduced dexterity, reduced grip strength, and locked grip. Many of the reports are derived from symptoms reported by exposed persons rather than signs detected by physicians and could

**Table 11 Proposed Sensorineural Stages of Effects of Hand-Transmitted Vibration**

| Stage | Symptoms |
|---|---|
| $0_{SN}$ | Exposed to vibration but no symptoms |
| $1_{SN}$ | Intermittent numbness with or without tingling |
| $2_{SN}$ | Intermittent or persistent numbness, reduced sensory perception |
| $3_{SN}$ | Intermittent or persistent numbness, reduced tactile discrimination, and/or manipulative dexterity |

Source: From Brammer et al., (1987).

be a reflection of neurological problems (Griffin and Bovenzi, 2002).

Muscle activity may be of great importance to tool users since a secure grip can be essential to the performance of the job and the safe control of the tool. The presence of vibration on a handle may encourage the adoption of a tighter grip than would otherwise occur and a tight grip may increase the transmission of vibration to the hand. If the chronic effects of vibration result in reduced grip, this may sometimes help to protect operators from further effects of vibration, but interfere with both work and leisure activities.

### 5.2.4 Articular Disorders

Many surveys of the users of hand-held tools have found evidence of bone and joint problems, most often among men operating percussive tools such as those used in metal-working jobs and mining and quarrying. It is speculated that some characteristic of such tools, possibly the low-frequency shocks, is responsible. Some of the reported injuries relate to specific bones and suggest the existence of cysts, vacuoles, decalcification, or other osteolysis and degeneration or deformity of the carpal, metacarpal, or phalangeal bones. Osteoarthrosis and olecranon spurs at the elbow and other problems at the wrist and shoulder are also documented.

Notwithstanding the evidence of many research publications, there is not universal acceptance that vibration is a common cause of articular problems and there is currently no dose–effect relation that predicts their occurrence. In the absence of specific information, it seems that adherence to current guidance for the prevention of vibration-induced white finger may provide reasonable protection.

### 5.2.5 Other Effects

Effects of hand-transmitted vibration may not be confined to the fingers, hands, and arms: many studies have found a high incidence of problems such as headaches and sleeplessness among tool users and have concluded that these symptoms are caused by hand-transmitted vibration. Although these are real problems to those affected, they are subjective effects that are not accepted as real by all researchers. Some current research is seeking a physiological basis for such symptoms. It would appear that caution is appropriate, but it is reasonable to assume that the adoption of the modern guidance to prevent vibration-induced white finger will also provide some protection from any other effects of hand-transmitted vibration within, or distant from, the hand.

### 5.3 Preventative Measures

Protection from the effects of hand-transmitted vibration requires actions from management, tool manufacturers, technicians, and physicians at the workplace and from tool users. Table 12 summarizes some of the actions that may be appropriate.

When there is reason to suspect that hand-transmitted vibration may cause injury, the vibration at tool–hand interfaces should be determined (by measurement or

**Table 12 Some Preventative Measures to Consider When Persons are Exposed to Hand-Transmitted Vibration**

| Group | Action |
| --- | --- |
| Management | Seek technical advice |
| | Seek medical advice |
| | Warn exposed persons |
| | Train exposed persons |
| | Review exposure times |
| | Policy on removal from work |
| Tool manufacturers | Measure tool vibration |
| | Design tools to minimize vibration |
| | Ergonomic design to reduce grip force, etc. |
| | Design to keep hands warm |
| | Provide guidance on tool maintenance |
| | Provide warning of dangerous vibration |
| Technical at workplace | Measure vibration exposure |
| | Provide appropriate tools |
| | Maintain tools |
| | Inform management |
| Medical | Pre-employment screening |
| | Routine medical checks |
| | Record all signs and reported symptoms |
| | Warn workers with predisposition |
| | Advise on consequences of exposure |
| | Inform management |
| Tool user | Use tool properly |
| | Avoid unnecessary vibration exposure |
| | Minimize grip and push forces |
| | Check condition of tool |
| | Inform supervisor of tool problems |
| | Keep warm |
| | Wear gloves when safe to do so |
| | Minimize smoking |
| | Seek medical advice if symptoms appear |
| | Inform employer of relevant disorders |

Source: Adapted from Chapter 19 of *The Handbook of Human Vibration* (Griffin, 1990).

by seeking information from other sources, e.g., the tool manufacturer). It will then be possible to predict whether the tool or process is likely to cause injury and whether any other tool or process could give a lower vibration severity. The duration of exposure to vibration should also be quantified. Reduction of exposure time may include the provision of exposure breaks during the day and, if possible, prolonged periods away from vibration exposure. For any tool or process having a vibration magnitude sufficient to cause injury, there should be a system to quantify and control the maximum daily duration of exposure to vibration in any individual.

Gloves are sometimes recommended as a means of reducing the adverse effects of vibration on the hands. International Standard 10819 (ISO, 1996) defines the requirements of *anti-vibration gloves*, but the standard has limitations and cannot be considered a reliable indication of whether a glove is beneficial (Griffin, 1998a). When using the frequency weightings in current standards, most commonly available gloves do *not* normally provide effective attenuation of the vibration on most tools. Gloves and cushioned handles may reduce the transmission of high frequencies of vibration, but current standards imply that these frequencies are not usually the primary cause of disorders. Gloves may protect the hand from other forms of mechanical injury (e.g., cuts and scratches) and protect the fingers from temperature extremes. Warm hands are less likely to suffer an attack of finger blanching and some consider that maintaining warm hands while exposed to vibration may also lessen the damage caused by the vibration.

Workers who are exposed to vibration magnitudes sufficient to cause injury should be warned of the possibility of vibration injuries and educated on the ways of reducing the severity of their vibration exposures. They should be advised of the symptoms to look out for and told to seek medical attention if the symptoms appear. There should be pre-employment medical screening wherever a subsequent exposure to hand-transmitted vibration may reasonably be expected to cause vibration injury. Medical supervision of each exposed person should continue throughout employment at suitable intervals, possibly annually.

### 5.4 Standards for Evaluation of Hand-Transmitted Vibration

There are standards method for measuring, evaluating, and assessing hand-transmitted vibration.

#### 5.4.1 Vibration Measurement

International standards 5349-1 (ISO, 2001) and 5349-2 (ISO, 2002) give general methods of measuring hand-transmitted vibration on tools and processes. Care is required to obtain representative measurements of tool vibration with appropriate operating conditions. There can be difficulties in obtaining valid measurements using some commercial instrumentation (especially when there are high shock levels). It is wise to determine acceleration spectra and inspect the acceleration time-histories before accepting the validity of any measurements.

#### 5.4.2 Vibration Evaluation

All current national and international standards use the same frequency weighting (called $W_h$) to evaluate hand-transmitted vibration over the approximate frequency range 8 to 1000 Hz (Figure 11; Griffin, 1997). This weighting is applied to measurements of vibration acceleration in each of the three axes of vibration at the point of entry of vibration to the hand. More recent standards suggest the overall severity of hand-transmitted vibration should be calculated from root-sums-of-squares of the frequency-weighted acceleration in the three axes.
**Figure 11** Frequency weighting $W_h$ for evaluation of hand-transmitted vibration.

The standards imply that if two tools expose the hand to vibration for the same period of time, the tool having the lowest frequency-weighted acceleration will be least likely to cause injury or disease.

Occupational exposures to hand-transmitted vibration can have widely varying daily exposure durations—from a few seconds to many hours. Often, exposures are intermittent. To enable a daily exposure to be reported simply, the standards refer to an equivalent 8-h exposure:

$$a_{\mathrm{hw(eq,8h)}} = A(8) = a_{\mathrm{hw}} \left[ \frac{t}{T_{(8)}} \right]^{1/2}$$

where $t$ is the exposure duration to an r.m.s. frequency-weighted acceleration, $a_{\mathrm{hw}}$, and $T(8)$ is 8 h (in the same units as $t$).

### 5.4.3 Vibration Assessment According to International Standard 5349 (ISO, 2001)

In an informative annex of ISO 5349-1 (ISO, 2001) there is a suggested relation between the lifetime exposure to hand-transmitted vibration, $D_y$ (in years), and the 8-h energy-equivalent daily exposure $A(8)$ for the conditions expected to cause 10% prevalence of finger blanching (Figure 12):

$$D_y = [A(8)]^{-1.06}$$

The percentage of affected persons in any group of exposed persons will not always correspond to the values shown in Figure 12: the frequency weighting, the time-dependency and the dose-effect information are based on less than complete information and they have been simplified for practical convenience. Additionally, the number of persons affected by vibration will depend on the rate at which persons enter and leave the exposed group. The complexity of the above equation implies far greater precision than is possible: a more convenient estimate of the years of exposure (in the range 1 to 25 years) required for 10% incidence of finger blanching is:

$$D_y = \frac{30.0}{A(8)}$$

**Figure 12** Relation between daily $A(8)$ and years of exposure expected to result in 10% incidence of finger blanching according to ISO 5349 (ISO, 2001). A 10% probability of finger blanching is predicted after 12 years at the EU exposure action value and after 5.8 years at the EU exposure limit value.

This equation gives the same result as the equation in the standard (to within 14%) and there is no information suggesting it is less accurate.

The informative annex to International Standard 5349 (ISO, 2001, p. 15) states: "Studies suggest that symptoms of the hand-arm vibration syndrome are rare in persons exposed with an 8-h energy-equivalent vibration total value, $A(8)$, at a surface in contact with the hand, of less than 2 m/s$^2$ and unreported for $A(8)$ values less than 1 m/s$^2$." However, this sentence should be interpreted with caution in view of the very considerable doubts over the frequency weighting and time-dependence in the standard (Griffin et al., 2003).

### 5.4.4 EU Machinery Safety Directive

The Machinery Safety Directive of the European Community (2006/42/EC) requires that instruction handbooks for hand-held and hand-guided machinery specify the equivalent acceleration to which the hands or arms are subjected where this exceeds a stated value (currently a frequency-weighted acceleration of 2.5 m s$^{-2}$ r.m.s.) (European Parliament and the Council of the European Union, 2006). Very many hand-held vibrating tools exceed this value. Standards defining test conditions for the measurement of vibration on many tools (e.g., chipping and riveting hammers, rotary hammers and rock drills, grinding machines, pavement breakers, chain saws) have been defined, e.g., ISO 8662 (1988) and ISO 28927 (2009).

### 5.4.5 EU Physical Agents Directive (2002)

For hand-transmitted vibration, the EU Physical Agents Directive defines an 8-h equivalent exposure action value of 2.5 m s$^{-2}$ r.m.s. and an 8-h equivalent exposure limit value of 5.0 m s$^{-2}$ r.m.s. (Figure 13) (European Parliament and the Council of the European Union, 2002). The Directive says workers shall not be exposed above the exposure limit value. If the
**Figure 13** Hand-transmitted vibration exposure limit value [$A(8) = 5.0$ m s$^{-2}$ r.m.s.] and 'exposure action value' [$A(8) = 2.5$ m s$^{-2}$ r.m.s.] in the EU Physical Agents (vibration) Directive.

exposure action values are exceeded, the employer shall establish and implement a program of technical and/or organizational measures intended to reduce to a minimum exposure to mechanical vibration and the attendant risks. The Directive requires that workers exposed to mechanical vibration in excess of the exposure action values shall be entitled to appropriate health surveillance. However, health surveillance is not restricted to situations where the exposure action value is exceeded: health surveillance is required if there is any reason to suspect that workers may be injured by the vibration, even if the action value is not exceeded.

According to ISO 5349-1 (ISO, 2001), the onset of finger blanching would be expected in 10% of persons after 12 years at the EU exposure action value and after 5.8 years at the exposure limit value (see Figure 12). The exposure action value and the exposure limit value in the EU Directive do not define safe exposures to hand-transmitted vibration (Griffin, 2004).

# CHAPTER 23

# SOUND AND NOISE: MEASUREMENT AND DESIGN GUIDANCE*

**John G. Casali**
**Virginia Polytechnic Institute and State University**
**Blacksburg, Virginia**

## 1 INTRODUCTION

Sound along with its subset, noise, which is often defined as unwanted sound, is a phenomenon that confronts human factors professionals in many settings and applications. A few examples are (1) an auditory warning signal, for which the proper sound parameters must be selected for maximizing detection, identification, and localization; (2) a situation wherein the speech communication that is critical between operators is compromised in its intelligibility by environmental noise, and therefore redesign of the communications system and/or acoustic environment is needed; (3) a residential community is intruded upon by the noise from vehicular traffic or a nearby industrial plant, causing annoyance and sleep arousal and necessitating abatement; (4) an in-vehicle auditory display that warns of dangerous conditions must convey urgency and localization cues; (5) a worker is exposed to hazardous noise on the job, and to prevent hearing loss, an appropriate hearing protection device (HPD) must be selected; and (6) a soldier's ears must be protected from exposure to gunfire with an HPD, but at the same time, he or she must be able to detect enemy threat-related sounds. To deal effectively with examples of these types, the human factors engineer must understand the basics of sound, instrumentation, and techniques for its measurement and quantification, analyses of acoustic measurements for ascertaining the audibility of signals and speech as well as the risks to hearing, and countermeasures to combat the deleterious effects of noise. In this chapter these and related matters are addressed from a human factors engineering perspective while several important noise-related standards and regulations are also covered.

---

* Portions of this chapter are based in part on Casali and Gerges (2006) and Robinson and Casali (2003).

At the outset it should be noted that the science of acoustics and the study of sound and noise within it is very broad and comprises a vast body of research and standards literature. Thus, as the subject of a single chapter, this topic cannot be covered in great depth herein. It is therefore an intent of this chapter to introduce several major topics concerning sound/noise, particularly as it impacts humans, and to point the reader to other publications for detail on specific topics. As for the area of sound/noise as a whole, three excellent, broad coverage texts are Kryter (1994), Crocker (1998), and Berger et al. (2003).

## 2 SOUND AND NOISE

Most aspects of acoustics rely on accurate quantification and evaluation of the sound itself; therefore, a basic understanding of sound parameters and sound measurement is needed before delving into application-oriented issues.

### 2.1 Fundamental Parameters

*Sound* is a disturbance in a medium (in industry, home, or recreational settings, most commonly air or a conductive structure such as a floor or wall) that has mass and elasticity. For example, an exhaust fan on the roof of an industrial plant has blades that rotate in the air, creating noise which may propagate into the surrounding community. Because the blades are coupled to the air medium, they produce pressure waves that consist of alternating compressions (above ambient air pressure) and rarefactions (below ambient pressure) of air molecules, the *frequency* ( $f$ ) of which is the number of above/below ambient pressure cycles per second, or *hertz* ( $Hz$ ). The reciprocal of frequency, $1/f$, is the *period* of the waveform. The waveform propagates outward from the fan as long as it continues to rotate, and the disturbance in air pressure that occurs in relation to ambient air pressure is heard as sound, in this case "fan roar." The linear distance traversed by the sound wave in one complete cycle of vibration is the *wavelength*:

$$\lambda = c/f \qquad (1)$$

Wavelength ( $\lambda$ in meters or feet) depends on the sound frequency ( $f$ in hertz) and velocity ( $c$ in meters per second or feet per second; in air at 68°F and pressure of 1 atmosphere (atm), 344 m/s or 1127 ft/s) in the medium. The speed of sound is influenced by the temperature of the medium, and in air it increases about 1.1 ft/s for each increase of 1°F.

*Vibrations* are oscillations in solid media and are often associated with the production of sound waves. *Noise* can be loosely defined as a subset of sound; that is, noise is sound that is undesirable or offensive in some aspect. However, the distinction is largely situation- and listener-specific, as perhaps best stated in the old adage "one person's music is another's noise."

Unlike some common ergonomics-related stressors such as repetitive motions or awkward lifting maneuvers, noise is a physical stimulus that is readily measurable and quantifiable using transducers (microphones)

and instrumentation [sound level meters (SLMs) and their variants] that are commonly available. Aural exposure to noise and the damage potential therefrom are functions of the *total energy* transmitted to the ear. In other words, the energy is equivalent to the product of the noise intensity and duration of the exposure. Several metrics that relate to the energy of the noise exposure have been developed, most with an eye toward accurately reflecting the exposures that occur in industrial or community settings. These metrics are covered in Section 3.2, but first, the most basic unit of measurement must be understood, the *decibel*.

### 2.2 Physical Quantification: Sound Levels and the Decibel Scale

The unit of *decibel*, one-tenth of a *bel*, is the most common metric applied to the quantification of noise amplitude. The decibel (dB) is a measure of *level*, defined as the logarithm of the ratio of a quantity to a reference quantity of the same type. In acoustics, it is applied to sound level, of which there are three types.

*Sound power level*, the most basic quantity, is typically expressed in decibels and is defined as

$$\text{Sound power level (dB)} = 10 \log_{10} \text{Pw}_1/\text{Pw}_r \qquad (2)$$

where $\text{Pw}_1$ is the acoustic power of the sound in watts or other power unit and $\text{Pw}_r$ is the acoustic power of a reference sound in watts, usually taken to be the acoustic power at hearing threshold for a young, healthy ear at the frequency of maximum sensitivity, the quantity $10^{-12}$ W.

*Sound intensity level*, following from power level, is typically expressed in decibels and is defined as

$$\text{Sound intensity level (dB)} = 10 \log_{10} I_1/I_r \qquad (3)$$

where $I_1$ is the acoustic intensity of the sound in watts per square meter or other intensity unit and $I_r$ is the acoustic intensity of a reference sound in watts per square meter, usually taken to be the acoustic intensity at hearing threshold, or the quantity $10^{-12}$ W/m². 

Within the last decade, sound measurement instruments to measure sound *intensity* level have become commonplace, albeit expensive and relatively complex. Sound *power* level, by contrast, is not directly measurable but can be computed from empirical measures of sound intensity level or sound pressure level. On the other hand, sound *pressure* level is directly measurable by using relatively straightforward instruments and is by far the most common metric used in practice.

*Sound pressure level* (SPL), abbreviated in formulas as $L_P$, is also typically expressed in decibels. Since power is directly proportional to the square of the pressure, SPL is defined as

$$\text{Sound pressure level (SPL or } L_P; \text{ dB)}$$
$$= 10 \log_{10} P_1^2/P_r^2 = 20 \log_{10} P_1/P_r \qquad (4)$$

where $P_1$ is the pressure level of the sound in micro-pascals (μPa) or other pressure unit and $P_r$ is the

pressure level of a reference sound in micropascals, usually taken to be the pressure at hearing threshold, or the quantity 20 μPa, or 0.00002 Pa. Other equivalent reference quantities are 0.0002 dyn/cm$^2$ and 20 μbars.

The application of the decibel scale to acoustic measurements yields a convenient means of collapsing the vast range of sound pressures which would be required to accommodate sounds that can be encountered into a more manageable, compact range. As shown in Figure 1, using the logarithmic compression produced by the decibel scale, the range of typical sounds from human hearing threshold to the threshold of tactile "feeling" is 120 dB, while the linear pressure scale applied to the same range of sounds produces a range of 1,000,000 Pa. Of course, sounds *do* occur that are higher than 120 dB (e.g., artillery fire) or lower than 0 dB (below normal threshold on an audiometer). A comparison of decibel values of example sounds to their pressure values (in pascals) is also depicted in Figure 1.

In considering changes in sound level measured in decibels, a few numerical relationships emanating from the decibel formulas above are often helpful in practice. An increase (decrease) in SPL by 6 dB is equivalent to a doubling (halving) of the sound pressure. Similarly, on the power or intensity scales, an increase (decrease) of 3 dB is equivalent to a doubling (halving) of the sound power or intensity. The latter relationship gives

rise to what is known as the *equal-energy rule* or *trading relationship*. Because sound represents energy which is itself a product of intensity and duration, an original sound that increases (decreases) by 3 dB is equivalent in total energy to the same original sound that does not change in decibel value but decreases (increases) in its duration by half (twice).

## 2.3 Basic Computations with Decibels

There are many practical instances in which it is helpful to predict the combined result of several individual sound sources that have been measured separately in decibels. This can be performed for random, uncorrelated sound sources using the equation

$$L_{P\text{combo}}(\text{dB})$$
$$= 10 \, \log_{10} \left( 10^{L_{P1}/10} + 10^{L_{P2}/10} + \cdots + 10^{L_{Pn}/10} \right) \tag{5}$$

and it applies for any decibel weighting (dBA, dBC, etc., as explained later) or for any bandwidth (such as one-third octave, full octave, etc.). For example, suppose that an industrial plant currently exposes workers in a work area to a time-weighted average (TWA) of 83.0 dBA, which is below the Occupational Safety and Health Administration (OSHA, 1983) action level (85.0 dBA)

**Sound Pressure Level (dB) re 20 μPa**
(*logarithmic scale*)
Range: Factor of 120 dB

| | dB | Pa | |
|---|---|---|---|
| Jackhammer, operator's position | 120 | 20 | |
| Chainsaw, cutting, operator's position | 110 | 10 | |
| Drag race car, unmuffled, 100 ft | 100 | 5 / 2 | DANGER |
| Power mower, muffled, operator position | 90 | 1 / 0.5 | |
| Electric razor, at ear | 80 | 0.2 | RISK |
| Vacuum cleaner, operator's position | 70 | 0.1 / 0.05 | |
| Conversation, 3 ft apart | 60 | 0.02 | ANNOYANCE |
| Computer fan, operator's position | 50 | 0.01 / 0.005 | |
| Quiet bedroom | 40 | 0.002 | |
| Recording studio | 30 | 0.001 / 0.0005 | |
| Very soft whisper, at ear | 20 | 0.0002 | |
| Wristwatch, ticking, at arm's length | 10 | 0.0001 / 0.00005 | |
| Threshold of hearing for healthy ear | 0 | 0.00002 | |

**Sound Pressure (Pa)**
(*linear scale*)
Range: Factor of 1,000,000 Pa

**Figure 1**   Sound pressure level in decibels and sound pressure in pascals for typical sounds.

at which a hearing conservation program would be required by law. Two new pieces of equipment are proposed for purchase and installation in this area: a new single-speed conveyor that has a constant noise output of 78.0 dBA and a new compressor that has a constant output of 82.5 dBA. The combined sound level will be approximately

$$
\begin{aligned}
L_{P\,\text{combo}} & (\text{dB}) \\
& = 10\,\log_{10}\left(10^{83.0/10} + 10^{78.0/10} + 10^{82.5/10}\right) \\
& = 86.4\,\text{dBA}
\end{aligned}
$$

Thus, by purchasing this conveyor, the plant would move from a noise exposure level (83.0 dBA) that is in compliance with OSHA to one that is not (86.4 dBA). This is one illustration why industries should adhere to a "buy quiet" policy, so that noise exposure problems are not created unknowingly by equipment purchases.

Subtraction of decibels works in the same manner as addition:

$$
L_{P\,\text{difference}}(\text{dB}) = 10\,\log_{10}\left(10^{L_{P1}/10} - 10^{L_{P2}/10}\right) \quad (6)
$$

Using the example above, if the compressor were eliminated from the situation, the overall combined noise level would be the combination of the three sources as computed to be 86.4 dBA, reduced by the absence of the compressor at 82.5 dBA:

$$
\begin{aligned}
L_{P\,\text{difference}}\,(\text{dB}) & = 10\,\log_{10}\left(10^{86.4/10} - 10^{82.5/10}\right) \\
& = 84.1\,\text{dBA}
\end{aligned}
$$

With this result, the plant area noise level moves back into OSHA compliance under the action level of 85.0 dBA, but just by about 1.0 dBA. To err on the safe side, especially to accommodate the potential of any upward fluctuations in noise level, this plant's management should still look to reduce the noise further or install a hearing conservation program.

There are a few rules of thumb that arise from the computations shown above. One is that when two sound sources are approximately equivalent in SPL, the combination of the two will be about 3 dB larger than the decibel level of the *higher* source. Another is that as the difference between two sounds exceeds about 13 dB, the contribution of the lower level sound to the combined sound level is negligible (i.e., about 0.2 dB). In relation to this, when it is desirable to measure a sound of interest in isolation but it cannot be physically separated from a background noise, the question becomes: To what extent is the background noise influencing the accuracy of the measurement? In many cases, such as in some manufacturing plants, the background noise cannot be turned off but the sound of interest can. If this is the case, then the sound of interest is measured in the background noise, and then the background noise is measured alone. If the background noise measurement differs from the combined measurement by more than 13 dB, then it has not influenced the measurement of the sound of interest in a significant manner. If the difference is

smaller, then equation (6) can be applied to correct the measurement, effectively by removing the background noise's contribution. Some standards use a difference of 10 dB as a guideline for when to apply the background noise correction.

Finally, it is important to recognize that due to the limits in precision and reliability of decibel measurements, for the applications discussed in this chapter (and most others in acoustics as well), it is unnecessary to record decibel calculations that result from the formulas herein to greater than one decimal point, and it is usually sufficient to round final results to the nearest 0.5 dB or even to integer values. However, to avoid interim rounding error, it is important to carry the significant figures through each step of the formulas until the end result is obtained (Ostergaard, 2003).

## 3 MEASUREMENT AND QUANTIFICATION OF SOUND AND NOISE EXPOSURES

### 3.1 Basic Instrumentation

Measurement and quantification of sound levels and noise exposure levels provide the fundamental data for assessing hearing exposure risk, speech and signal-masking effects, hearing conservation program needs, and engineering noise control strategies. A vast array of instrumentation is available; however, for most of the aforementioned applications, a basic understanding of three primary instruments (SLMs, dosimeters, and real-time spectrum analyzers) and their data output will suffice. In instances where noise is highly impulsive in nature, such as gunfire, and/or development of situation-specific engineering noise control solutions is anticipated, more specialized instruments may be necessary.

Because sound is propagated as pressure waves that vary over space and in time, a complete acoustic record of a noise exposure or a sound event that has a prolonged duration requires simultaneous measurements at all points of interest in the sound field. This measurement should occur over a representative, continuous time period to document the noise level exhaustively in the space. Obviously, this is typically cost- and time-prohibitive, so one must resort to sampling strategies for establishing the observation points and intervals. The analyst must also decide whether detailed, discrete-time histories with averaging over time and space are needed (such as with a noise-logging *dosimeter*), if discrete samples taken with a short-duration moving time average (with a basic *sound level meter*) will suffice, or if frequency-band-specific SPLs are needed for selecting noise abatement materials (with a *spectrum analyzer*). A discussion of these three primary types of sound measurement instruments and the noise descriptors that can be obtained therefrom follows.

### 3.1.1 Sound Level Meter

Most sound measurement instruments derive from the basic SLM, a device for which there are four grades and associated performance tolerances that become more stringent as the grade number *decreases*, described by

American National Standards Institute (ANSI) S1.4-1983(R2006) (ANSI, 2006). Type 0 instruments have the most stringent tolerances and are for laboratory use only. Other grades include type 1, intended for precision measurement in the field or laboratory; type 2, intended for general field use, especially where frequencies above 10,000 Hz are not prevalent; and type S, a special-purpose meter that may perform at grade 1, 2, or 3 but may not include all of the operational functions of the particular grade. A grade of type 2 or better is needed for measuring occupational exposures and community noise and to obtain data for most court proceedings. For SLMs which provide time-averaged or integrated SPLs or, optionally, sound exposure levels for OSHA or other noise-monitoring requirements, ANSI S1.43-1997(R2007) should be consulted (ANSI, 2007a). This standard specifies SLM characteristics that are essential to the accurate measurement of steady, intermittent, fluctuating, and impulsive sounds, particularly when the measurement obtained is over a time interval as opposed to instantaneously.

A block diagram of the functional components of a generic SLM appears in Figure 2. At the top, a microphone/preamplifier senses the pressure changes caused by an airborne sound wave and converts the pressure signal into a voltage signal. Because the pressure fluctuations of a sound wave are small in magnitude, the corresponding voltage signal must be preamplified and then input to an amplifier, which boosts the signal before it is processed further. The passband, the range of frequencies that are passed through and processed, of a

high-quality SLM contains frequencies from about 10 to 20,000 Hz, but depending on the frequency weighting used, not all frequencies are treated in the same way. A selectable frequency-weighting network, or filter, is then applied to the signal. These networks most commonly include the A-, B-, and C-weighting functions shown in Figure 3b. For OSHA noise-monitoring measurements and for many community noise applications, the A scale, which deemphasizes the low frequencies and to a smaller extent the high frequencies, is used. In addition to the common A scale (which approximates the 40-phon level of hearing) and C scale (100-phon level), other selections may be available. If no weighting function is selected on the meter, the notation dBZ or dB(linear) is used, and all frequencies are processed without weighting factors. The actual weighting functions for the three suffix notations A, B, and C are superimposed on the phon contours of Figure 3a and are also depicted in Figure 3b as actual frequency-weighting functions.

Next (not shown), the signal is squared to reflect the fact that SPL in decibels is a function of the square of the sound pressure. The signal is then applied to an exponential averaging network, which defines the meter's dynamic response characteristics. In effect, this response creates a moving-window, short-time average display of the sound waveform. The two most common settings are FAST, which has a time constant of 0.125 s, and SLOW, which has a time constant of 1.0 s. These time constants were established decades ago to give analog needle indicators a rather sluggish response (particularly on the SLOW setting) so that they could be read by the human eye even when highly fluctuating sound pressures were measured. Under the FAST or SLOW dynamics, the meter indicator rises exponentially toward the decibel value of an applied constant SPL. For OSHA measurements, the SLOW setting is used, and this setting is also best when the average value (as it is changing over time) is desired. The FAST setting is more appropriate when the variability or range of fluctuations of a time-varying sound is desired. On certain SLMs, a third time constant, IMPULSE, may also be included for measurement of sounds that have sharp transient characteristics over time and are generally less than 1 s in duration, exemplified by gunshots or impact machinery such as drop forges. The IMPULSE setting has an exponential rise time constant of 35 ms and a decay time of 1.5 s. It is useful to afford the observer the time to view the maximum value of a burst of sound before it decays and is more commonly applied in community and business machine noise measurements than in industrial settings.

Because sound often consists of symmetrical pressure fluctuations above and below ambient air pressure for which the arithmetic average is zero, a *root mean square* (rms) averaging procedure is applied when FAST, SLOW, or IMPULSE measurements are taken, and the result is displayed in decibels. In effect, each pressure (or converted voltage) value is squared, the arithmetic mean of all squared values is then obtained, and finally the square root of the mean is computed to provide the rms value.

**Figure 2**  Functional components of a sound level meter.
**Figure 3** (*a*) Equal-loudness contours based on the psychophysical phon scale, with sound level meter frequency-weighting curves superimposed; (*b*) decibels vs. frequency values of A, B, and C sound level meter weighting curves. (Adapted with permission from Earshen, 1986.)

Some SLMs include an unweighted PEAK setting that does not utilize the rms computation but instead provides an indication of the actual peak SPL reached during a pressure impulse. This measurement mode is necessary for certain applications: for instance, to determine if the OSHA limit of 140 dB for impulsive exposure is exceeded. A type 1 or 2 meter must be capable of measuring a 50-μs pulse. It is important to note that the aforementioned rms-based IMPULSE dynamics setting is unsuitable for measurement of PEAK SPLs.

With regard to the final component of a SLM shown in Figure 2, the indicator display or readout, much debate has existed over whether an analog (needle pointer or bar "thermometer-type" linear display) or

digital (numeric) display is best. Ergonomics research indicates that, although the digital readout affords higher precision of information to be presented in a smaller space, its disadvantage is that the least significant digit becomes impossible to read when the sound level is fluctuating rapidly. Also, it is more difficult with a digital readout for the observer to capture the maximum and minimum values of a sound, as is often desirable using the FAST or IMPULSE response. On the other hand, if very precise measurements down to a fraction of a decibel are needed, the digital indicator is preferable as long as the meter incorporates an appropriate time integrating/averaging feature or "hold" setting so that the data values can be captured. Because of the advantages and

disadvantages of each type of display, some contemporary SLMs include both analog and digital readouts.

***Microphone Considerations***   Most SLMs have interchangeable microphones that offer varying frequency response, sensitivity, and directivity characteristics (Peterson, 1979). The *response* of the microphone is the ratio of electrical output (in volts) to the sound pressure at the diaphragm of the microphone. Sound pressure is commonly expressed in pascals for free-field conditions (where there are no sound reflections resulting in reverberation), and the free-field voltage response of the microphone is given as millivolts per pascal. When specifications for *sensitivity* or *output level* are given, the response is usually based on a pure-tone sound wave input. Typically, the output level is provided in decibels re 1 V at the microphone electrical terminals, and the reference sensitivity is 1 V/Pa.

Most microphones that are intended for general sound measurements are essentially *omnidirectional* (i.e., nondirectional) in their response for frequencies below about 1000 Hz. The 360° response pattern of a microphone is called its *polar response*, and the pattern is generally symmetrical about the axis perpendicular to the diaphragm. Some microphones are designed to be highly directional, of which one example is the cardiode design, which has a heart-shaped polar response wherein the maximum sensitivity is for sounds whose direction of travel causes them to enter the microphone at 0° (or the *perpendicular incidence response*), and minimum sensitivity is for sounds entering at 180° behind the microphone. The response at 90°, where sound waves travel and enter parallel to the diaphragm, is known as the *grazing incidence response*. Another response pattern, the *random-incidence response*, represents the mean response of the microphone for sound waves that strike the diaphragm from all angles with equal probability. This response characteristic is the most versatile, and thus it is the response pattern used most often in the United States. Frequency responses for various microphone incidence patterns are depicted in Figure 4.

Because most U.S. SLM microphones are omnidirectional and utilize the random-incidence response, it is best for an observer to point the microphone at the primary noise source and hold it at an angle of incidence from the source at approximately 70°. This will produce a measurement most closely corresponding to the random-incidence response. On the other hand, free-field microphones have their flattest response at normal incidence (0°), while pressure microphones have their flattest response at grazing incidence (90°), and both should be pointed accordingly with respect to the noise source. Care must be taken to avoid shielding the microphone with the body or other structures. The response of microphones can also vary with temperature, atmospheric pressure, and humidity, with temperature usually being the most critical factor. Most microphone manufacturers supply correction factors for variations in decibel readout due to temperature effects. Atmospheric effects are generally significant only when measurements are made in aircraft or at very high altitudes, and humidity has a negligible effect except at very high levels. In any case, microphones must not be exposed

**Figure 4**   Frequency response of a hypothetical microphone for three angles of incidence. (Adapted with permission from Peterson, 1979.)

to moisture or large magnetic fields, such as those produced by transformers. When used in windy conditions, a foam windscreen should be placed over the microphone. This will reduce the contaminating effects of wind noise while influencing the frequency response of the microphone only slightly at high frequencies. The windscreen offers the additional benefit of protection of the microphone from damage due to being struck and/or from airborne foreign matter.

**Sound Level Meter Applications** It is important to note that the basic SLM is intended to measure sound levels at a given moment in time, although certain specialized devices can perform integration or averaging of sound levels over an extended period of time. When the nonintegrating/nonaveraging SLM is used for long-term noise measurements, such as over a workday, it is necessary to sample and make multiple manual data entries on a record to characterize the exposure. Being difficult, both in terms of reading the meter and recording sound level data, this technique is usually best limited to area measurements and is not applied to an individual's exposure sampling. Furthermore, the sampling process becomes more difficult as the fluctuations in a noise become more rapid and/or random in nature. SLMs are useful for determining the levels of human speech in both rms or peak values, calibration of laboratory experiments, calibration of audiometers (with special attachments), and community noise event-related measurements.

### 3.1.2 Dosimeter

The *audio-dosimeter* is a portable battery-powered device that is derived directly from a SLM but also features the ability to obtain special measures of noise exposure (discussed later) that relate to regulatory compliance and hearing hazard risk. Some versions are weather resistant and can be used outdoors to log a record of noise in a community setting, including both event-related, short-term measures and long-term averages and other statistical data.

Dosimeters for industrial use are very compact and are generally worn on the belt or in the pocket of an employee, with the microphone generally clipped to the lapel or shoulder of a shirt or blouse. The intent is to obtain a noise exposure history over the course of a full or partial work shift and to obtain, at a minimum, a readout of the TWA exposure and noise dose for the period measured. Depending on the features, the dosimeter may provide a running histogram of noise levels on a short-time-interval (such as 1-min) basis, compute statistical distributions of the noise exposures for the period, flag and record exposures that exceed OSHA maxima of 115 dBA continuous or 140 dB PEAK, and compute average metrics using 3 dB, 5 dB, or even other time-versus-level exchange rates. The dosimeter eliminates the need for the observer to set up a discrete sampling scheme, follow a noise-exposed worker, or monitor continuously an instrument that is staged outdoors, all of which are necessary with a conventional SLM. Dosimeters are special versions of integrating/averaging SLMs, which are governed by ANSI S1.43-1997(R2007), as referenced in ANSI (2007a) herein.

### 3.1.3 Spectrum Analyzer

A *spectrum analyzer* is an advanced SLM which incorporates selective frequency-filtering capabilities to provide an analysis of the noise level as a function of frequency. In other words, the noise is broken down into its frequency components and a distribution of the noise energy in all measured frequency bands is available. Bands are delineated by upper and lower edge or cutoff frequencies and a center frequency. Different widths and types of filters are available, with the most common width being the *octave filter*, wherein the center frequencies of the filters are related by multiples of 2 (i.e., 31.5, 63, 125, 250,..., 4000, 8000, and 16,000 Hz), with the most common type being the center-frequency proportional, wherein the width of the filter depends on the center frequency (as in an octave filter set, in which the passband width equals the center frequency divided by $2^{1/2}$). The *octave band*, commonly called the 1/1-octave filter, has a center frequency (CF) that is equal to the geometric mean of the upper ($f_u$) and lower ($f_l$) cutoff frequencies. The formulas to compute the center frequency for the octave filter, as well as the band-edge frequencies, are

$$\text{CF} = (f_u f_l)^{1/2}$$
$$\text{Upper cutoff, } f_u = \text{CF} \cdot 2^{1/2} \qquad (7)$$
$$\text{Lower cutoff, } f_l = \text{CF}/2^{1/2}$$

More precise spectral resolution can be obtained with other center-frequency proportional filter sets with narrower bandwidths, the most common being the 1/3 octave, and with constant-percentage bandwidth filter sets, such as 1% or 2% filters. Note that in both types the filter bandwidth increases as the center frequency increases. Still other analyzers have constant-bandwidth filters, such as 20-Hz-wide bandwidths which are of constant width regardless of center frequency. Whereas in the past most spectrum analyzer filters have been analog devices with "skirts" or overshoots extending slightly beyond the cutoff frequencies, digital computer-based analyzers are now very common. These "computational" filters use fast Fourier transform (FFT) or other algorithms to compute sound level in a prespecified band of fixed resolution. FFT devices can be used to obtain very high resolutions of noise spectral characteristics using bandwidths as low as 1 Hz. However, in most measurement applications, a 1/1- or 1/3-octave analyzer will suffice unless the noise has considerable power in near-tonal components that must be isolated. One caution is in order: If a noise fluctuates in time and/or frequency, an integrating/averaging analyzer should be used to achieve good accuracy of measurements. It is important that the averaging period be long in comparison to the variability of the noise being sampled.

*Real-time analyzers* incorporate parallel banks of filters (not FFT driven) that can process all frequency bands simultaneously, and the signal output may be controlled by a SLOW, FAST, or other time constant setting, or it may be integrated or averaged over a fixed

time period to provide $L_{\text{OSHA}}$, $L_{\text{eq}}$, or other average-type measurements to be discussed later.

***Spectrum Analyzer Applications***   While occupational noise is monitored with a dosimeter or SLM for the purpose of OSHA noise exposure compliance (using A-weighted broadband measurement) or the assessment of hearing protection adequacy (using C-weighted broadband measurement), both of these applications can also be addressed (in some cases more accurately) with the use of spectral measurements of the noise level. For instance, the OSHA Occupational Noise Exposure Standard (OSHA, 1983) allows the use of octave-band measurements reduced to broadband dBA values to determine if noise exposures exceed dBA limits defined in Table G-9 of the standard. Furthermore, Appendix B of the standard concerns hearing protector adequacy and allows the use of an octave-band method for determining, on a spectral rather than a broadband basis, whether a hearing protector is adequate for a particular noise spectrum. It is also noteworthy that spectral analysis can help the hearing conservationist discriminate noises as to their hazard potential even though they may have similar A-weighted SPLs. This is illustrated in Figure 5, where both noises would be considered to be of equal hazard by the OSHA-required dBA measurements (since they both are 90 dBA), but the 1/3-octave analysis demonstrates that the lowermost noise is more hazardous, as evidenced by the heavy concentration of energy in the midrange and high frequencies.

One of the most important applications of the spectrum analyzer is to obtain data that will provide the basis for engineering noise control solutions. For instance, to select an absorption material for lining interior surfaces of a workplace, the spectral content of the noise must be known so that the appropriate density, porosity, and thickness of material may be selected.

Spectrum analyzers are also necessary for performing the frequency-specific measurements needed to predict either signal audibility or speech intelligibility in noisy situations, according to the techniques discussed in Section 7. Furthermore, they can be applied for calibration of signals for laboratory experiments and audiometers, for determining the frequency response and other quality-related metrics for systems designed for music and speech rendition, and for determining certain acoustic parameters of indoor spaces, such as reverberation time.

***dBC–dBA***   Lacking a spectrum analyzer, one can obtain a very rough indication of the dominant spectral content of a noise by using a SLM and taking measurements in both dBA and dBC for the same noise. If the dBC–dBA value is large, that is, about 5 dB or more, then it can be concluded that the noise has considerable low-frequency content. If, on the other hand the dBC–dBA value is negative, the noise clearly has strong midrange components, since the A-weighting curve exhibits slight amplification in the range 2000–4000 Hz. Such rules of thumb rely on the differences in the C- and A- weighting curves shown in Figure 3*b*. However, they should not be relied upon in lieu of a spectrum analysis if the noise is believed to have high-frequency or narrowband components that need noise control attention.

### 3.1.4   Acoustic Calibrators

Each of the instruments described above contains a microphone that transduces the changes in pressure and inputs this signal into the electronics. Although modern sound measurement equipment is generally stable and reliable, calibration is necessary to match the microphone to the instrument so that the accuracy of the measurement is assured. Because of its susceptibility to varying environmental conditions and damage due

**Figure 5**   Spectral differences for two different noises that have the same dBA value.

to rough handling, moisture, and magnetic fields, the microphone is generally the weakest link in the measurement equipment chain. Therefore, an acoustic calibrator should be applied before and after each measurement with a SLM. The pretest calibration ensures that the instrument is indicating the correct SPL for a standard reference calibrator output at a specified SPL and frequency (e.g., 94 dB at 1000 Hz). The posttest calibration is done to determine if the instrumentation, including the microphone, has drifted during the measurement and, if so, if the drift is large enough to invalidate the data obtained. Calibrators may be electronic transducer-type devices with loudspeaker outputs from an internal oscillator, or "pistonphones," which use a reciprocating piston in a closed cavity to produce sinusoidal pressure variations as the cylinder volume changes. Both types include adapters that allow the device to be mated to microphones of different diameters. Calibrators should be sent to the manufacturer at least annually for bench calibration and certification.

There are many other issues that bear on the proper application of sound level measurement equipment, such as microphone selection and placement, averaging time and sampling schemes, and statistical data reduction techniques, all of which are beyond the scope of this chapter. For further coverage of these topics, the reader is referred to the acoustics texts of Harris (1991) and Berger et al. (2003).

## 3.2 Sound and Noise Metrics

### 3.2.1 Exchange or Trading Rates

Because both sound amplitude and sound duration determine the energy of an *exposure*, average-type measures are based on simple algorithms or *exchange rates*, which trade amplitude for time and vice versa. For example, most noise regulations, OSHA (1983) or otherwise, stipulate that a worker's exposure may not exceed a maximum daily accumulation of noise energy. In other words, in OSHA terms the product of duration and intensity must remain under the regulatory cap or *permissible exposure limit* (PEL) of 90 dBA TWA for an 8-h work period, which is equivalent to a 100% noise dose. Much debate has occurred over the past several decades about which exchange rate is most appropriate for prediction of hearing damage risk, and most countries currently use either a 3- or 5-dB relationship. The OSHA exchange rate is 5 dB, which means that an increase (decrease) in decibel level by 5 dB is equivalent (in exposure) to a doubling (halving) of time. For instance, using the OSHA PEL of 90 dBA for 8 h, if a noise is at 95 dBA, the allowable exposure per workday is half of 8 h, or 4 h. If a noise is at 85 dBA, the allowable exposure time is twice 8 h, or 16 h. These allowable reference exposure durations (*T* values) are provided in Table A-1 of the OSHA (1983) regulation or they may be computed using the formula for *T,* which appears below as equation (14). The 5-dB exchange rate is predicated in part on the theory that intermittent noise is less damaging than continuous noise because some recovery from temporary hearing loss occurs during quiet periods. Arguments against it include the fact that an

exchange of 5 dB for a factor of 2 in time duration has no real physical basis in terms of energy equivalence. Furthermore, there is some evidence that the quiet periods of intermittent noise exposures are insufficient in length to allow for recovery to occur. The 5-dB exchange rate is used for all measures associated with OSHA regulations, including the most general average measure of $L_{OSHA}$, the TWA referenced to an 8-h duration, and noise dose in percent.

Most European countries use a 3-dB exchange rate, also known as the aforementioned *equal-energy rule*. In this instance, a doubling (halving) of sound intensity, which corresponds to a 3-dB increase (decrease), equates (in energy) to a doubling (halving) of exposure duration. The equal energy concept stems from the fact that if sound intensity is doubled or halved, the equivalent sound intensity level change is 3 dB. An exposure to 90 dBA for 8 h using a 3-dB exchange rate is equivalent to a 120-dBA exposure of only 0.48 min. Because each increase in decibels by 10 corresponds to a 10-fold increase in intensity, the 30-dB increase from 90 to 120 dBA represents a 1000-fold ($10^3$) increase in sound intensity, from 0.001 to 1 W/m$^2$. The 90-dBA exposure period is 8 h, or 480 min, and this must be reduced by the same factor as the SPL increase, so $480/1000 = 0.48$ min, or 29 s. The 3-dB exchange rate is used for all measures associated with the equivalent continuous sound level, $L_{eq}$.

### 3.2.2 Average and Integrated SPLs

As discussed earlier, conventional SLMs provide "momentary" decibel measurements that are based on very short moving-window exponential averages using FAST, SLOW, or IMPULSE time constants. However, since the majority of noises fluctuate over time, one of several types of average measurements, discussed below, is usually most appropriate as a descriptor of the central tendency of the noise. Averages may be obtained in one of two ways: (1) by observing and recording conventional SLM readouts using a short-time-interval sampling scheme and then manually computing the average value from the discrete values or (2) by using a SLM or dosimeter which automatically calculates a running-average value using microprocessor circuitry which provides either a true continuous integration of the area under the sound pressure curve or which obtains discrete samples of the sound at a very fast rate and computes the average, per ANSI (2007a) S1.43-1997(R2007). Generally, average measures obtained by method 2 yield more representative values because they are based on continuous or near-continuous sampling of the waveform, which the human observer cannot perform well even with continuous vigilance.

The average metrics discussed below are generally considered as the most useful for evaluating noise hazards in industry, annoyance potential in the community, and other sounds in the laboratory or in the field which fluctuate over time. In most cases for industrial hearing conservation as well as community noise annoyance purposes, the metrics utilize the A-weighting scale. For precise spectral measurements with no frequency weighting, the decibel unweighted (linear) scale may be

applied in the measurements. The equations are all in a form where the data values are considered to be discrete sound levels. Thus, they can be applied to data from conventional SLMs or dosimeters. For continuous sound levels (or when the equations are used to describe true integrating meter functioning), the $\sum$ sign in the equations would be replaced by the integral sign $\int_0^T$ and the $t_i$ replaced by $dt$. Variables used in the equations are as follows:

$L_i$ = decibel level in measurement interval $i$

$N$ = number of intervals

$T$ = total measurement time period

$t_i$ = length of measurement interval $i$

$Q$ = exchange rate (dB)

$q = Q/\log_{10}(2)$ $\begin{cases} \text{for 3-dB exchange, } q = 10.0 \\ \text{for 4-dB exchange, } q = 13.29 \\ \text{for 5-dB exchange, } q = 16.61 \end{cases}$

The general form equation for *average SPL*, or $L_{\text{average}}$, $L_{\text{av}}$, is

$$L_{\text{av}}(Q) = q\,\log_{10}\left[\frac{1}{T}\sum_{i=1}^{N}\left(10^{Li/q}\,t_i\right)\right] \qquad (8)$$

The *equivalent continuous sound level*, $L_{\text{eq}}$, equals the continuous sound level which when integrated or averaged over a specific time would result in the same energy as a variable sound level over the same time period. The equation for $L_{\text{eq}}$, which uses a 3-dB exchange rate, is

$$L_{\text{eq}} = L_{\text{av}}(3) = 10\,\log_{10}\left[\frac{1}{T}\sum_{i=1}^{N}\left(10^{Li/10}t_i\right)\right] \qquad (9)$$

In applying the $L_{\text{eq}}$, the individual $L_i$ values are usually in dBA. Equation (9) may also be used to compute the overall equivalent continuous sound level (for a single site or worker) from individual $L_{\text{eq}}$ values that are obtained over contiguous time intervals by substituting the $L_{\text{eq}}$ values in the $L_i$ variable. The $L_{\text{eq}}$ values are often expressed with the time period over which the average is obtained; for instance, $L_{\text{eq}}(24)$ is an equivalent continuous level measured over a 24-h period. Another average measure that is derived from $L_{\text{eq}}$ and often used for community noise quantification is $L_{\text{dn}}$, which is simply a 24-h $L_{\text{eq}}$ measurement with a 10-dB penalty added to all nighttime noise levels from 10 P.M. to 7 A.M. The rationale for the penalty is that humans are more disturbed by noise, especially due to sleep arousal, during nighttime periods.

The equation for the *OSHA average noise level*, $L_{\text{OSHA}}$, which uses a 5-dB exchange rate, is

$$L_{\text{OSHA}}(5) = 16.61\,\log_{10}\left[\frac{1}{T}\sum_{i=1}^{N}\left(10^{L_{iA}/16.61}t_i\right)\right] \qquad (10)$$

where $L_{iA}$ is in dBA, slow response.

OSHA's TWA is a special case of $L_{\text{OSHA}}$ which requires that the total time period always be 8 h, that time is expressed in hours, and that sound levels below 80 dBA, termed the *threshold level*, are not included in the measurement:

$$\text{TWA} = 16.61\,\log_{10}\left[\frac{1}{8}\sum_{i=1}^{N}\left(10^{L_{iA}/16.61}t_i\right)\right] \qquad (11)$$

where $L_{iA}$ is in dBA, slow response, and $T$ is always 8 h. Only $L_{iA} \geq 80$ dBA is included.

OSHA's *noise dose* is a percentage representation of the noise exposure, where 100% is the maximum allowable dose, corresponding to a 90-dBA TWA referenced to 8 h. Dose utilizes a *criterion sound level*, which is presently 90 dBA, and a *criterion exposure period*, which is presently 8 h. A noise dose of 50% corresponds to a TWA of 85 dBA, and this is known as the OSHA *action level*. Calculation of dose, $D$, is as follows:

$$D = \frac{100}{T_c}\sum_{i=1}^{N}\left(10^{(L_{iA}-L_c)/q}t_i\right) \qquad (12)$$

where $L_{iA}$ is in dBA, slow response, $L_c$ is the criterion sound level, and $T_c$ is the criterion exposure duration. Only $L_{iA} \geq 80$ dBA is included.

Noise dose $D$ can also be expressed as follows for a constant sound level over the workday:

$$D = 100\left(\frac{C_1}{T_1} + \frac{C_2}{T_2} + \cdots + \frac{C_n}{T_n}\right) \qquad (13)$$

where $C_i$ is the total time (h) of actual exposure at $L_i$, $T_i$ is total time (h) of reference-allowable exposure at $L_i$, from Table G-16a of OSHA, (1983), and $C_i/T_i$ represents a partial dose at sound level $i$.

The *reference allowable* exposure $T$ for a given sound level can also, in lieu of consulting Table G-16a in OSHA (1983), be computed as

$$T = 8/2^{(L-90)/5} \qquad (14)$$

where $L$ is the measured dBA level.

Two other useful equations to compute dose $D$ from TWA and vice versa are

$$D = 100 \times 10^{(\text{TWA}-90)/16.61} \qquad (15)$$

$$\text{TWA} = [16.61\,\log_{10}(D/100)] + 90 \qquad (16)$$

where $D$ is the dose in percent. TWA can also be found for each value of dose $D$ in Table A-1 of OSHA (1983).

A final measure that is particularly useful for quantifying the exposure due to single or multiple occurrences of an acoustic event (such as a complete operating cycle of a machine, a vehicle drive-by, or an aircraft flyover) is the *sound exposure level* (SEL). The SEL represents a sound 1 s in length that imparts the

same acoustic energy as a varying or constant sound that is integrated over a specified time interval $t_i$ in seconds. Over $t_i$, an $L_{eq}$ is obtained which indicates that SEL is used only with a 3-dB exchange rate. A reference duration of 1 s is applied for $t_0$ in the following equation for SEL:

$$\text{SEL} = L_{eq} + 10 \log_{10}(t_i/t_0) \qquad (17)$$

where $L_{eq}$ is the equivalent SPL measured over time period $t_i$.

Detailed example problems and solutions using the formulas above may be found in Casali and Robinson (1999).

## 4 INDUSTRIAL NOISE REGULATION AND ABATEMENT

### 4.1 Need for Attention to Noise

In this section the discussion will concentrate on the management of noise in industry, because that is the major source of noise exposure for most people, and as such, it constitutes a very common threat toward noise-induced hearing loss (NIHL). Many of the techniques for measurement, engineering control, and hearing protection also apply to other exposures, such as those encountered in recreational or military settings. The need for attention to industrial noise is indicated when (1) noise creates sufficient intrusion and operator distraction such that job performance and even job satisfaction are compromised; (2) noise creates interference with important communications and signals, such as interoperator communications, machine- or process-related aural cues, alerting/emergency signals, or military tactics and missions; and/or (3) noise exposures constitute a hazard for NIHL in workers.

### 4.2 OSHA (and Other) Noise Exposure Regulated Limits

In U.S. workplaces, while a few industrial hearing conservation programs were voluntarily implemented by a few industries in the 1940s and 1950s (Berger, 2003a), legal limits on general industrial noise exposure and application of hearing protection were not promulgated into law until May of 1971, and this occurred with the Occupational Noise Exposure Standard of the Occupational Safety and Health Act. The OSHA noise standard was the first requirement, based on exposure levels, for noise abatement and hearing protection devices (HPDs) in the general industry (OSHA, 1971a), and a similar law was promulgated for construction (OSHA, 1971b), these settings being where the great majority of U.S. citizens were and continue to be at risk for hearing loss due to noise exposure.

In 1983, some 12 years after the original OSHA legislation on noise in industry, the legal advent of the OSHA Hearing Conservation Amendment (OSHA, 1983) for General Industry immediately caused the proliferation of HPDs in U.S. industrial workplaces because this amendment required a choice of HPDs to be *supplied* to any worker exposed to above an 85 dBA TWA,

or 50% noise dose, for an 8-h workday, with the measurement taken on the "slow" scale and using a 5-dB exchange rate between exposure dBA level and time of exposure. Other industries, including airline, truck and bus carriers, railroads, and oil and gas well drilling, developed separate, and generally less comprehensive, noise and hearing conservation regulations than those of OSHA (1971a, 1983) for general industry, and unfortunately, to date, there has never been an analogue to the OSHA Hearing Conservation Amendment of 1983 adopted into law for the construction industry, where noise levels are often high and auditory warning signals (e.g., vehicle backup alarms) are prevalent (Casali and Alali, 2009). Finally, in the mining industry, noise exposure limits and hearing protection were addressed in that industry's regulation, first under the Federal Coal Mine Health and Safety Act of 1969 and later under the Federal Mine Safety and Health Amendments Act of 1977. In 1999, the Mine Safety and Health Administration (MSHA) issued a more comprehensive noise regulation that governed all forms of mining (MSHA, 1999).

In regard to combating the hearing loss problem in OSHA terms, if the noise dose (in general industry) exceeds the OSHA action level of 50%, which corresponds to an 85-dBA TWA, the employer must institute a *hearing conservation program* (HCP) which consists of several facets (OSHA, 1983). If the criterion level of 100% dose is exceeded (which corresponds to the permissible exposure level (PEL) of 90-dBA TWA for an 8-h day), the regulations specifically state that steps must be taken to reduce the employee's exposure to the PEL or below via administrative work scheduling and/or the use of engineering controls. It is stated specifically that HPDs must be provided if administrative and/or engineering controls fail to reduce the noise to the PEL. Therefore, in applying the letter of the law, HPDs are only intended to be relied on when administrative or engineering controls are infeasible or ineffective. The final OSHA noise-level requirement pertains to impulsive or impact noise, which is not to exceed a PEAK SPL limit of 140 dB.

### 4.3 Hearing Conservation Programs

#### 4.3.1 Shared Responsibility: Management, Workers, and Government

A successful HCP depends on the shared commitment of management and labor as well as the quality of services and products provided by external noise control consultants, audiology or medical personnel who conduct the hearing measurement program, and vendors (e.g., hearing protection suppliers). Involvement and interaction of corporate positions such as the plant safety engineer, ergonomist, occupational nurse, noise control engineer, purchasing director, and manufacturing supervisor are important. Furthermore, government regulatory agencies, such as OSHA and MSHA, have a responsibility to maintain and disseminate up-to-date noise exposure regulations and HCP guidance, to conduct regular in-plant compliance checks of noise exposure and quality of HCPs, and to provide enforcement where noise control and/or hearing protection is inadequate. Finally, the

"end user" of the HCP, that is, the worker, must be an informed and motivated participant. For instance, if a fundamental component of the HCP is the personal use of HPDs, the effectiveness of the program in preventing NIHL will depend most heavily on the worker's commitment to wear the HPD properly and consistently. Failure by any of these groups to carry out their responsibilities can result in HCP failure and worker hearing loss. Side benefits of a successful HCP may include a marked reduction in noise-induced distractions and interference on the job and an improvement in worker comfort and morale.

### 4.3.2 Hearing Conservation Program Components

Hearing conservation in industry should be thought of as a strategic, programmatic effort that is initiated, organized, implemented, and maintained by the employer, with cooperation from other parties as indicated above. A well-accepted approach is to address the noise exposure problem from a *systems* perspective, wherein empirical noise measurements provide data input which drives the implementation of countermeasures against the noise (including engineering controls, administrative strategies, and personal hearing protection). Subsequently, noise and audiometric data, which reflect the effectiveness of those countermeasures, serve as feedback for program adjustments and improvements. A brief discussion of the major elements of a HCP, as dictated by OSHA (1983), follows.

*Monitoring*   Noise exposure monitoring is intended to identify employees for inclusion in the HCP and to provide data for the selection of HPDs. The data are also useful for identifying areas where engineering noise control solutions and/or administrative work scheduling may be necessary. All OSHA-related measurements, with the exception of the PEAK SPL limit, are to be made using a SLM or dosimeter (of at least ANSI type 2) set on the dBA scale, SLOW response, using a 5-dB exchange rate, and incorporating all sounds whose levels are from 80 to 130 dBA. It is unspecified, but it must be assumed that sounds above 130 dBA should also be monitored. (Of course, such noise levels represent OSHA noncompliance since the maximum allowable continuous sound level is 115 dBA.) Appendix G of the OSHA regulation suggests that monitoring be conducted at least once every one or two years. Related to the noise-monitoring requirement is that of notification. Employees must be given the opportunity to observe the noise-monitoring process, and they must be notified when their exposures exceed the 50% dose (85-dBA TWA) level.

*Audiometric Testing Program*   All employees whose noise exposures are at the 50% dose level or above must be included in a pure-tone audiometric testing program wherein a baseline audiogram is completed within six months of the first exposure, and subsequent tests are done on an annual basis. Annual audiograms are compared against the baseline to determine if the worker has experienced a *standard threshold shift* (STS), which

is defined by OSHA (1983). The annual audiogram may be adjusted for age-induced hearing loss (presbycusis) using the gender-specific correction data in Appendix F of the regulation. All OSHA-related audiograms must include 500, 1000, 2000, 3000, 4000, and 6000 Hz, in comparison to most clinical audiograms, which typically extend from 125 to 8000 Hz. If an STS is revealed, a licensed physician or audiologist must review the audiogram and determine the need for further audiological or otological evaluation, the employee must be notified of the STS, and the selection and proper use of HPDs must be revisited.

*Training Program and Record Keeping*   An essential component of an HCP is a training program for all noise-exposed workers. Training elements to be covered include the effects of noise on hearing; purpose, selection, and use of HPDs; and purpose and procedures of audiometric testing. Also, accurate records must be kept of all noise exposure measurements, at least from the last two years, as well as audiometric test results for the duration of the worker's employment. It is important, but not required by OSHA, that noise and audiometric data be used as feedback for improving the program. For example, noise exposure records may be used to identify machines that need maintenance attention, to assist in the relocation of noisy equipment during plant layout efforts, to provide information for future equipment procurement decisions, and to target plant areas that are in need of noise control intervention. Some employers plot noise levels on a "contour map," delineating floor areas by their decibel levels. When monitoring indicates that the noise level in a particular contour has changed, it is taken as a sign that the machinery and/or work process has changed in the area and that further evaluation may be needed.

*Hearing Protection Devices*   The OSHA Hearing Conservation Amendment (OSHA, 1983) requires that a selection of HPDs that are suitable for the noise and work situation must be made available to all employees whose TWA exposures meet or exceed 85 dBA. Such HPDs are also useful outside the workplace, for the protection of hearing against noises produced by power tools, lawn care equipment, recreational vehicles, target shooting and hunting, spectator events, ordnance and various military weapons, as well as many other exposures. Complete overviews of conventional HPDs which provide noise attenuation via passive (nonelectronic) means may be found in Berger (2003b) and Gerges and Casali (2007). Following is a brief overview of the basic types of devices, primarily adopted from the book chapter by Gerges and Casali (2007).

   *Earplugs* consist of vinyl, silicone, spun fiberglass, cotton/wax combinations, and open-cell or closed-cell foam products that are inserted into the ear canal to form a noise-blocking seal. Proper fit to the user's ears and training in insertion procedures are critical to the success of earplugs. A related device is the *semi-insert* or *ear canal cap*, which consists of earplug-like pods that are positioned at the rim of the ear canal and held in place by a lightweight headband. The headband is

useful for storing the device around the neck when the user moves out of the noise. *Earmuffs* consist of earcups, usually of a rigid plastic material with an absorptive liner, that enclose the outer ear completely and seal around it with foam- or fluid-filled cushions. A headband connects the earcups, and on some models this band is adjustable so that it can be worn over the head, behind the neck, or under the chin, depending on the presence of other headgear, such as a welder's mask. In general terms, as a group, earplugs provide better attenuation than earmuffs below about 500 Hz and equivalent or greater protection above 2000 Hz (Gerges and Casali, 2007). At intermediate frequencies, earmuffs sometimes have the advantage in attenuation. Earmuffs are generally more easily fit by the user than either earplugs or canal caps, and depending on the temperature and humidity of the environment, the earmuff can be uncomfortable (in hot or high-humidity environments) or a welcome ear insulator (in a cold environment). Semi-inserts (canal caps) generally offer less attenuation and comfort than earplugs or earmuffs, but because they are readily storable around the neck, they are convenient for those workers who frequently move in and out of noise.

Conventional styles of passive earplugs and earmuffs generally exhibit a spectral profile of attenuation that is nonlinear with respect to sound frequency; that is, the attenuation generally increases with increased frequency. At any given frequency, the most attenuation that any HPD can provide, also termed its "theoretical limit," is the bone conduction threshold of the wearer. This is because at sound levels above the bone conduction threshold the HPD is "flanked" by the bone conduction pathway to the sensory portion of the ear and sound enters the ear through structural-borne vibrations of the skull (Berger, 2003b).

Beginning in the mid-1980s, conventional passive HPDs were augmented with new features, such as attenuation spectra which are uniform or "flat" as a function of frequency, attenuation capabilities that increase as a function of increases in incident sound level (termed "amplitude-sensitive" or "level-dependent" devices), adjustable attenuation as achieved with adjustable continuous valves or discrete dampers inside a vent running through the HPD, and passive noise attenuators achieved using one-end-closed tube structures that provide quarter-wave resonance to cancel offending noise in a narrow frequency band. All of these passive HPD augmentations, along with research results on their performance, are covered in detail in Casali (2010a). Furthermore, battery-powered or "active" electronic HPD features began to appear in the 1980s, including active noise cancellation that incorporates "anti-noise" of inverted phase relationship with the noise to be cancelled (primarily effective below about 1000 Hz), electronically-modulated sound transmission devices which provide microphone pickup of sounds external to the HPD and output-limited, amplified pass-through of signals and speech within a certain passband through the HPD, and military/law enforcement-oriented tactical communications and protection systems (TCAPS) which provide covert two-way communications, signal pass-through capabilities, and gunfire-responsive protection. All versions of these active electronic HPDs are reviewed in Casali (2010b), along with research data on their performance in various applications.

Regardless of their type, HPD effectiveness depends heavily on the proper fitting and use of the devices (Park and Casali, 1991). Therefore, the employer is required to provide training in the fitting, care, and use of HPDs to all employees affected (OSHA, 1983). Hearing protector use becomes mandatory when the worker has not undergone the baseline audiogram, has experienced an STS, or has a TWA exposure that meets or exceeds 90 dBA. In the case of the worker with an STS, the HPD must attenuate the noise to 85 dBA TWA or below. Otherwise, the HPD must reduce the noise to at least 90 dBA TWA.

The protective effectiveness or adequacy of an HPD for a given noise exposure must be determined by applying the attenuation data as currently required by the U.S. Environmental Protection Agency (EPA, 1979) to be included on protector packaging. These data are obtained from psychophysical threshold tests at nine 1/3-octave bands with centers from 125 to 8000 Hz that are performed on human subjects, and the difference between the thresholds with the HPD on and without it constitutes the attenuation at a given frequency. Spectral attenuation statistics (means and standard deviations) and the single-number noise reduction rating (NRR) which is computed therefrom are provided. The ratings are the primary means by which end users compare different HPDs on a common basis and make determinations of whether adequate protection and OSHA compliance will be attained for a given noise environment.

The most accurate method of determining HPD adequacy is to use octave-band measurements of the noise and the spectral mean and standard deviation attenuation data to determine the protected exposure level under the HPD. This is called the *National Institute for Occupational Safety and Health* (*NIOSH*) *long method* or *octave-band method*. Computational procedures appear in NIOSH (1975). Because this method requires octave-band measurements of the noise, preferably with each noise band's data in TWA form, the data requirements are large and the method is not widely applied in industry. However, because the noise spectrum is compared against the attenuation spectrum of the HPD, a "matching" of exposure to protector can be obtained; therefore, the method is considered to be the most accurate available.

The NRR represents a means of collapsing the spectral attenuation data into one broadband attenuation estimate that can easily be applied against broadband dBC or dBA TWA noise exposure measurements. In calculation of the NRR, the mean attenuation is reduced by two standard deviations; this translates into an estimate of protection theoretically achievable by 98% of the population (EPA, 1979). The NRR is intended primarily to be subtracted from the dBC exposure TWA to estimate the protected exposure level in dBA:

$$\text{Workplace TWA (dBC)} - \text{NRR}$$
$$= \text{protected TWA (dBA)} \qquad (18)$$

Unfortunately, because OSHA regulations require that noise exposure monitoring be performed in dBA, the dBC values may not be readily available to the hearing conservationist. In the case where the TWA values are in dBA, the NRR can still be applied, albeit with some loss of accuracy. With dBA data, a 7-dB "safety" correction is applied to the NRR to account for the largest typical differences between C- and A-weighted measurements of industrial noise, and the equation is

$$\text{Workplace TWA (dBA)} - (\text{NRR} - 7)$$
$$= \text{protected TWA (dBA)} \quad (19)$$

Although the methods above are promulgated by OSHA (1983) for determining HPD adequacy for a given noise situation, a word of caution is needed. The data appearing on HPD packaging are obtained under optimal laboratory conditions with properly fitted protectors and trained human subjects. In no way does the "experimenter-fit" protocol and other aspects of the currently required (by the EPA) test procedure, ANSI S3.19-1974 (ANSI, 1974), represent the conditions under which HPDs are selected, fit, and used in the workplace (Park and Casali, 1991). *Therefore, the attenuation data used in the octave-band or NRR formulas shown above are, in general, inflated and cannot be assumed as representative of the protection that will be achieved in the field*. The results of a review of research studies in which manufacturers' on-package NRRs were compared against NRRs computed from actual subjects taken with their HPDs from field settings are shown in Figure 6. Clearly, the differences between laboratory and field estimates of HPD attenuation are large and the hearing conservationist must take this into account

when selecting protectors. Efforts by ANSI Working Group S12/WG11 has focused on the development of an improved testing standard, ANSI S12.6-1997(R2008) (ANSI, 2008), which has an important human factors provision in its "method B" for subject (not experimenter) fitting of the HPD and relatively naïve (not trained) subjects, as is the provision in ANSI S3.19-1974 (ANSI, 1974) and "method A" of the newer standard, ANSI S12.6-1997(R2008) (ANSI, 2008).

The method B testing protocol of ANSI S12.6-1997(R2008) has been demonstrated to yield attenuation data that are more representative of those achievable under workplace conditions wherein a high-quality HCP is operated. However, at press time for this chapter, the EPA was in the process of attempting to promulgate a comprehensive new federal law to govern the testing and labeling of all hearing protectors of various types. In the EPA's proposed rule (EPA, 2009), the basic test for obtaining the passive spectral attenuation of an HPD which is proposed for use in developing the HPD's noise reduction label relies on the use of the method A fitting technique of ANSI S12.6-1997(R2008), which has been demonstrated in the same or similar forms to produce attenuation values that are substantially *higher* than those achieved by actual users in field use (e.g., Berger, 2003b; Park and Casali, 1991). It remains to be seen, however, whether method A or B will be adopted in the EPA rule or whether any new rule will even be adopted into law. It is also important to note that the EPA's proposed rule (EPA, 2009) does have, for the first time in proposed U.S. law, provisions for much more complete testing and labeling of augmented hearing protectors that offer special capabilities, as compared to that which is available in the current EPA rule (EPA, 1979), which relies exclusively on the ANSI S3.19-1974 standard that

**Figure 6** Comparison of hearing protection device NRRs by device type: manufacturers' laboratory data vs. real-world "field" data. (Adapted with permission from Berger, 2003b.)

is limited to testing of conventional passive attenuation. In other words, assuming that the EPA's proposed rule is promulgated into law, the capabilities of active noise cancellation, active sound transmission, impulsive (e.g., gunfire) protection circuits, passive amplitude-sensitive devices, and other special augmentations will be tested and labeled as to their performance.

### 4.4 Engineering Noise Control

As discussed above, hearing protection and/or administrative controls are not a panacea for combating the risks posed by noise. They should not supplant noise control engineering; in fact, the best solution, in part because it does not rely on employee behavior, is to reduce the noise itself, preferably at the emission source. The physical reduction of the noise energy, either at its source, in its path, or at the worker, should be a major focus of noise management programs. However, in many cases where noise control is ineffective, infeasible (as on an airport taxi area), or prohibitively expensive, HPDs become the primary countermeasure.

There are many techniques used in noise control, and the specific approach must be tailored to the noise problem at hand. Spectrum analyzer measurements are typically used by noise control engineers in the selection of control strategies. Example noise control strategies are (1) *isolation of the source* via relocation, enclosure, or vibration damping using metal or air springs (below about 30 Hz) or elastomer (above 30 Hz) supports; (2) *reduction at the source or in the path* using mufflers or silencers on exhausts, reducing cutting, fan, or impact speeds, dynamically balancing rotating components, reducing fluid flow speeds and turbulence, absorptive foam or fiberglass on reflective surfaces to reduce reverberation, shields to reflect and redirect noise (especially high frequencies), and lining or wrapping of pipes and ducts; (3) *replacement or alteration of machinery*, including belt drives as opposed to noisier gears, electrical rather than pneumatic tools, and shifting frequency outputs such as by using centrifugal fans (low frequencies) rather than propeller or axial fans (high frequencies), keeping in mind that low frequencies propagate further than high frequencies, but high frequencies are more hazardous to hearing; and (4) *application of quieter materials*, such as rubber liners in parts bins, conveyors, and vibrators, resilient hammer faces, bumpers on material handling equipment, nylon slides or rubber tires rather than metal rollers, and fiber rather than metal gears. Further discussion of these and other techniques may be found in Driscoll and Royster (2003) and in Harris (1991), and an illustration of implementation possibilities in an industrial plant appears in Figure 7.

A final approach that has recently become available to industry is *active noise reduction* (ANR), in which an electronic system is used to transduce an offensive noise in a sound field and then process and feed back the noise into the same sound field such that it is exactly $180°$ out of phase with, but of equal amplitude to, the original noise. The superposition of the out-of-phase *anti-noise* with the original noise causes physical cancellation of the noise in a target zone of the workplace. For highly repetitive, predictable noises, synthesis of the anti-noise, as opposed to transduction and reintroduction, may also be used in a feedforward fashion. At frequencies below about 1000 Hz, the ANR technique is most effective, which is fortuitous since the passive noise control materials to combat low-frequency noise, such as absorptive liners and barriers, are typically heavy, bulky, and expensive. At higher frequencies and their corresponding shorter wavelengths, the processing and phase relationships become more complicated and cancellation is less successful, although the technology is improving rapidly and the bandwidth of effective ANR cancellation is increasing (Casali et al., 2004; Casali, 2010b).

In designing and implementing noise control hardware, it is important that ergonomics be taken into account. For instance, in a sound-treated booth to house an operator, the ventilation system, lighting, visibility outward to the surrounding work area, and other considerations relating to operator comfort and performance must be considered. With regard to noise-isolating machine enclosures, access provisions should be designed so as not to compromise the operator–machine interface. In this regard, it is important that both operation and maintenance needs be met. If noise control hardware creates difficulties for the operators in carrying out their jobs, they may tend to modify or remove it, rendering it ineffective.

## 5 AUDITORY EFFECTS OF NOISE

### 5.1 Hearing Loss in the United States

Noise-induced hearing loss (NIHL) is one of the most widespread occupational maladies in the United States, if not the world. In the early 1980s, it was estimated that over 9 million workers were exposed to noise levels averaging over 85 dBA for an 8-h workday (EPA, 1981). Today, this number is likely to be higher because the control of noise sources, in both type and number, has not kept pace with the proliferation of industrial and service sector development. Due in part to the fact that before the first OSHA noise exposure regulation of 1971 there were no U.S. federal regulations governing noise exposure in general industry, many workers over 50 years of age now exhibit hearing loss that results from the effects of occupational noise.

Of course, the total noise exposure from both occupational and nonoccupational sources determines the NIHL that a victim experiences. Of the estimated 28 million Americans who exhibit significant hearing loss due to a variety of etiologies, such as pathology of the ear and hereditary tendencies, over 10 million have losses that are directly attributable to noise exposure [National Institutes of Health (NIH), 1990]. Therefore, the noise-related losses are *preventable* in nearly all cases. The majority of losses are due to on-the-job exposures, but leisure noise sources do contribute a significant amount of energy to the total noise exposure of some people. Although the effects of noise exposure are serious and must be reckoned with by the safety professional, one
**Figure 7**    Noise control implementation in an industrial plant. (Adapted with permission from OSHA, 1980.)

fact is encouraging: Process/machine-produced noise, as well as most sources of leisure noise, are physical stimuli that can be avoided, reduced, or eliminated; therefore, NIHL is preventable with effective abatement and protection strategies. Total elimination of NIHL should thus be the only acceptable goal.

Noise-induced hearing loss is also a staggering problem in the military, especially during periods of war. Recent estimates from 2007 showed that since the Afghanistan war began in 2001 and the Iraq war in 2003, approximately 52% of combat soldiers

experienced moderately severe hearing loss or worse, primarily attributable to combat-related exposures [Defense Occupational and Environmental Health Readiness Data Repository (DOEHRS-DR), 2007]. Recent Army reports portray an even bleaker picture, with over *one-third* of U.S. soldiers who return from service in these two wars exhibiting permanent noise-induced hearing loss that is believed to be associated with military operations (Ahroon, 2007). Furthermore, the problem of noise-induced hearing loss is the *most common* military disability, as evidenced by over $1.2

billion spent on personnel hearing-related injuries in fiscal year 2006 alone (Saunders and Griest, 2009). This staggering cost included $786+ million for medical and hearing-assistive expenses associated with the noise-induced hearing impairment and $418+ million for the debilitating, life-pervasive tinnitus malady (persistent ringing or whistling in the ears). In fiscal year 2007, the U.S. Veterans Administration dispensed 348,920 hearing aids to veterans at a cost of approximately $141 million (Saunders and Griest, 2009). By comparison to these staggering annual expenditures relating to noise-induced hearing loss in the military, in industry the annual cost of disability payments for hearing-related injuries in about 30 million workers was about $242.4 million in 2001 (NIOSH, 2001). Part of the problem in military-related hearing loss is that warfighters may be inhibited from using hearing protection devices for fear that they may compromise their ability to maintain stealth, operate tactically, and hear threats. Therefore, improvements in hearing protection designs, particularly those that maintain or perhaps enhance the warfighter's situation awareness while simultaneously providing protection against gunfire and other noises, are much needed. More information on this subject may be found in the reviews of Casali (2010a,b).

## 5.2 Types and Etiologies of Noise-Induced Hearing Loss

Although the major concern of the industrial hearing conservationist is to prevent employee hearing loss that stems from occupational noise exposure, it is important to recognize that hearing loss may also emanate from a number of sources other than noise, including infections and diseases specific to the ear, most frequently originating in the middle or conductive portion; other bodily diseases, such as multiple sclerosis, which injures the neural part of the ear; ototoxic drugs, of which the mycin family is a prominent member; exposure to certain chemicals and industrial solvents; hereditary factors; head trauma; sudden hyperbaric- or altitude-induced pressure changes; and aging of the ear (presbycusis). Furthermore, not all noise exposure occurs on the job. Many workers are exposed to hazardous levels during leisure activities, from such sources as automobile/motorcycle racing, personal stereo headsets and car stereos, firearms, and power tools. The effects of noise on hearing are generally subdivided into acoustic trauma and temporary or permanent threshold shifts (Melnick, 1991).

### 5.2.1 Acoustic Trauma

Immediate organic damage to the ear from an extremely intense acoustic event such as an explosion is known as *acoustic trauma*. The victim will notice the loss immediately, and it often constitutes a permanent injury. The damage may be to the conductive chain of the ear, including rupture of the tympanum (eardrum) or dislodging of the ossicular chain (small bones and muscles) of the middle ear. Conductive losses can, in many cases, be compensated for with a hearing aid and/or surgically corrected. Neural damage may also occur, involving a dislodging of the hair cells and/or breakdown of the neural organ (Organ of Corti) itself. Unfortunately, neural loss is irrecoverable and not typically compensable with a hearing aid. Acoustic trauma represents a severe injury, but fortunately, its occurrence is relatively uncommon, even in industrial settings. However, it can occur due to sudden explosive-induced trauma in the military setting.

### 5.2.2 Noise-Induced Threshold Shift

A *threshold shift* is defined as an elevation of hearing level from a person's baseline hearing level and it constitutes a loss of hearing sensitivity. *Noise-induced temporary threshold shift* (NITTS), sometimes referred to as "auditory fatigue," is by definition recoverable with time away from the noise. Thus, elevation of threshold is temporary and usually can be traced to an overstimulation of the neural hair cells (actually, the stereocilia) in the Organ of Corti. Although the person may not notice the temporary loss of sensitivity, NITTS is a cardinal sign of overexposure to noise. It may occur over the course of a full workday in noise or even after a few minutes of exposure to very intense noise. Although the relationships are somewhat complex and individual differences are rather large, NITTS does depend on the level, duration, and spectrum of the noise as well as on the audiometric test frequency in question (Melnick, 1991).

With *noise-induced permanent threshold shift* (NIPTS), there is no possibility of recovery. NIPTS can manifest suddenly as a result of acoustic trauma; however, noises that cause NIPTS most typically constitute exposures that are repeated over a long period of time and have a cumulative effect on hearing sensitivity. In fact, the losses are often quite insidious in that they occur in small steps over a number of years of overexposure and the person may not be aware until it is too late. This type of exposure produces permanent neural damage, and although there are some individual differences as to magnitude of loss and audiometric frequencies affected, the typical pattern for NIPTS is a prominent elevation of threshold at the 4000-Hz audiometric frequency (sometimes called the 4-kHz notch), followed by a spreading of loss to adjacent frequencies of 3000 and 6000 Hz. From a classic study on workers in the jute weaver industry, Figure 8 depicts the temporal profile of NIPTS as the family of audiometric threshold shift curves, with each curve representing a different number of years of exposure. As noise exposure continues over time, the hearing loss spreads over a wider frequency bandwidth inclusive of midrange and high frequencies and encompassing the range of most auditory warning signals. In some cases, the hearing loss renders it unsafe or unproductive for the victim to work in certain occupational settings where the hearing of certain signals are requisite to the job. Unfortunately, the power of the consonants of speech sounds, which heavily influence the intelligibility of human speech, also lie in the frequency range that is typically affected by NIPTS, compromising the victim's ability to understand speech. This is the tragedy of NIPTS in that the worker's ability to communicate is hampered, often
**Figure 8** Cumulative auditory effects of years of noise exposure in a jute-weaving industry. (Adapted with permission from Taylor et al., 1964.)

severely and always irrecoverably. Hearing loss is a particularly troubling disability because its presence is not overt; therefore, the victim is often unintentionally excluded from conversations and may miss important auditory signals because others either are unaware of the loss or simply forget about the need to compensate for it.

### 5.3  Concomitant Auditory Injuries

Following exposure to high-intensity noise, some people will notice that ordinary sounds are perceived as "muffled," and in some cases, they may experience a ringing or whistling sound in the ears, known as *tinnitus*. These manifestations should be taken as serious indications that overexposure has occurred and that protective action should be taken if similar exposures are encountered in the future. Tinnitus may also occur by itself or in conjunction with NIPTS. Some people report that tinnitus is always present, pervading their lives. It thus has the potential to be quite disruptive and in severe cases debilitating.

More rare than tinnitus, but typically quite debilitating, is the malady known as *hyperacusis*, which refers to hearing that is extremely sensitive to sound. Hyperacusis can manifest in many ways, but a number of victims report that their hearing became painfully sensitive to sounds of even normal levels after exposure to a particular noise event. Therefore, at least for some, hyperacusis can be traced directly to noise exposure. Sufferers often must use HPDs when performing normal activities, such as walking on city streets, visiting movie theaters, or washing dishes in a sink, because such activities produce sounds that are painfully loud to them. It should be noted that hyperacusis sufferers often exhibit normal audiograms, even though their reaction to sound is one of hypersensitivity.

## 6  PERFORMANCE, NONAUDITORY, AND PERCEPTUAL EFFECTS OF NOISE

### 6.1  Performance and Nonauditory Health Effects

#### 6.1.1  Task Performance Effects

It is important to recognize that, among other deleterious effects, noise can degrade operator task performance. Research studies concerning the effects of noise on performance are primarily laboratory based and task/noise specific; therefore, extrapolation of the results to actual industrial settings is somewhat risky (Sanders and McCormick, 1993). Nonetheless, on the negative side, noise is known to mask task-related acoustic cues as well as to cause distraction and disruption of "inner speech"; on the positive side, noise may at least initially heighten operator arousal and thereby improve performance on tasks that do not require substantial cognitive processing (Poulton, 1978). To obtain reliable effects of noise on performance, except on tasks that rely heavily on short-term memory, the level of noise must be fairly high, usually 95 dBA or greater. Tasks that are simple and repetitive often show no deleterious performance effects (and sometimes improvements) in the presence of noise, whereas difficult tasks that rely on perception and information processing on the part of the operator will often exhibit performance degradation (Sanders and McCormick, 1993). It is generally accepted that unexpected or aperiodic noise causes greater degradation than predictable, periodic, or continuous noise, and the startle response created by sudden noise can be disruptive.

#### 6.1.2  Nonauditory Health Effects

Noise has been linked to physiological problems other than those of the hearing sense, including hypertension, heart irregularities, extreme fatigue, and digestive

disorders. Most physiological responses of this nature are symptomatic of stress-related disorders. Because the presence of high noise levels often induces other stressful feelings (such as sleep disturbance and interference with conversing in the home and fear of missing oncoming vehicles or warning signals on the job), there are second-order effects of noise on physiological functioning that are difficult to predict. The reader is referred to Kryter (1994) for a detailed discussion of nonauditory health effects of noise.

## 6.2 Annoyance Effects of Noise

Noise has frequently given rise to vigorous complaints in many settings, ranging from office environments to aircraft cabins to homes. Such complaints are manifestations of what is known as noise-induced *annoyance*, which has given rise to a host of products, such as white/pink noise generators for masking undesirable noise sources, noise-canceling headsets, and noise barriers for reducing sound propagation over distances and through walls. In the populated community, noise is a common source of disturbance, and for this reason many communities, both urban and rural, have noise ordinances and/or zoning restrictions which regulate the maximum noise levels that can result from certain sources and/or in certain land areas. In communities that have no such regulations, residents who are disturbed by noise sources such as industrial plants or spectator events often have no other recourse than to bring civil lawsuits for remedy (Casali, 1999). The principal rationale for limiting noise in communities is to reduce sleep and speech interference and to avoid annoyance (Driscoll et al., 2003). Some of the measurement units and instrumentation discussed in this chapter are useful for community and other noise annoyance applications, while more detailed information on the subject may be found in Fidell and Pearsons (1997), Casali (1999), and Driscoll et al. (2003).

## 6.3 Loudness and Related Scales of Measurement

One of the most readily identified aspects of a sound or noise and one that relates to a majority of complaints, be it a theater actor's voice which is too quiet or a background noise which is too intense, is that of *loudness*. As discussed above, the decibel is useful for quantifying the amplitude of a sound on a physical scale; however, it does not yield an absolute or relative basis for quantifying the human *perception* of sound amplitude, commonly called *loudness*. However, there are several psychophysical scales that are useful for measuring loudness, the two most prominent being *phons* and *sones*.

### 6.3.1 Phons

The decibel level of a 1000-Hz tone, which is judged by human listeners to be equally loud to a sound in question, is the phon level of the sound. The phon levels of sounds of different intensities are shown in Figure 3*a*; this family of curves is referred to as the *equal-loudness contours*. On any given curve, the combinations of

sound level and frequency along the curve produce sound experiences of equal loudness to the normal-hearing listener. Note that at 1000 Hz on each curve the phon level is equal to the decibel level. The threshold of hearing for a young, healthy ear is represented by the 0-phon-level curve. The young, healthy ear is sensitive to sounds between about 20 and 20,000 Hz, although, as shown by the curve, it is not equally sensitive to all frequencies. At low- and midlevel sound intensities, low-frequency and to a lesser extent high-frequency sounds are perceived as less intense than sounds in the range 1000–4000 Hz, where the undamaged ear is most sensitive. But as phon levels move to higher values, the ear becomes more linear in its loudness perception for sounds of different frequencies. It is because the ear exhibits this nonlinear behavior that the frequency-weighting responses for dBA, dBC, and so on, were developed, as discussed in Section 3.1.1.

### 6.3.2 Sones

Although the phon scale provides the ability to equate the loudness of sounds of various frequencies, it does not afford an ability to describe how much louder one sound is than another. For this, the *sone* scale is needed (Stevens, 1936). One sone is defined as the loudness of a 1000-Hz tone of 40-dB SPL. In relation to 1 sone, 2 sones are twice as loud, 3 sones are three times as loud, $\frac{1}{2}$ sone is half as loud, and so on. Phon level ($L_P$) and sones are related by the following formula for sounds at or above a 40-phon level:

$$\text{Loudness (sones)} = 2^{(L_P - 40)/10} \qquad (20)$$

According to equation (20), 1 sone equals 40 phons and the number of sones doubles with each 10-phon increase above 40; therefore, it is straightforward to conduct a comparative estimate of loudness levels of sounds with different decibel levels. The rule of thumb is that each 10-dB increase in a sound (i.e., one that is above 40 dB to begin with) will result in a doubling of its loudness. For instance, a home theater room that is currently at 50 dBA may be comfortable for listening to movies and classical music. However, if a new air-conditioning system increases the noise level in the room by 10 dBA, the occupants will experience a perceptual doubling of loudness and will probably complain about the interference with speech and music in the room. Once again, the compression effect of the decibel scale yields a measure that does not reflect the much larger influence that an increase in sound level will have on the human perception of loudness.

***Precise Calculation of Sone Levels by the Stevens Method*** It should be evident that sone levels can be calculated directly from psychological measurements in phons [per equation (20)] but not from physical measurements of SPL in decibels without special conversions. This is because the phon-based loudness and SPL relationship changes as a function of the sound frequency, and the magnitude of this change depends on the intensity of the sound. The *Stevens*

*method*, also known as the *ISO spectral method*, is fully described in Rossing (1990). Briefly, this method requires measurement of the dB (linear) level in 10 standard octave or 1/3-octave bands, with centers at 31, 63, 125, 250, 500, 1000, 2000, 4000, 8000, and 16000 Hz. Then, for each band measurement, the loudness index, $S_i$, is computed from Figure 9 as follows:

$$\text{Loudness level (sones)} = S_{max} + 0.3 \sum S_i \quad (21)$$

where $S_i$ is the loudness index from Figure 9, $S_{max}$ is the largest of the loudness indices, and $\sum S_i$ is the sum of the loudness indices for all bands except $S_{max}$. Using this "precise" method, the effect is to include the loudest band of noise at 100%, while the totality of the other bands is included at 30%. Obviously, because the noise

must be measured in octave or 1/3-octave bands, the method is measurement intensive and requires special instrumentation (i.e., a real-time spectrum analyzer).

***Approximation of Sone Levels from dBA***    In contrast to the Stevens method, the loudness of a sound in sones can be computed from dBA values, albeit with substantially less spectral precision. In this method, only a SLM (as compared to a spectrum analyzer) is needed, and measurements are captured in dBA. Then 1.5 sones is equated to 30 dBA, and the number of sones is doubled for each 10-dBA increase over 30 dBA. For example, 40 dBA = 3 sones, 50 dBA = 6 sones, 55 dBA = 8 sones, 60 dBA = 12 sones, 65 dBA = 16 sones, 70 dBA = 24 sones, 75 dBA = 32 sones, 80 dBA = 48 sones, 85 dBA = 64 sones, and 90 dBA = 96 sones (Rossing, 1990). This method is particularly accurate

**Figure 9**    Chart for calculating loudness indices from decibel levels in various frequency bands for use in computing sone levels. (Adapted with permission from Rossing, 1990.)

at low to moderate sound levels since the ear responds in similar sensitivity to the A-weighting curve at these levels.

***Practical Applications of the Sone*** Despite its practicality, the sone scale is not widely used (an exception is that household ventilation fans typically have voluntary sone ratings). However, it is the most useful scale for comparing different sounds as to their loudnesses as perceived by humans. Given its interval qualities, the sone is more useful than decibel measurements when attempting to compare the loudness of different products' emissions; for example, a vacuum cleaner that emits 60 sones is twice as loud as one of 30 sones. The sone also is useful in conveying sound loudness experiences to lay groups. An example of such use for illustrating the perceptual impacts of a community noise disturbance (automobile racetrack) to a civil court jury may be found in Casali (1999).

### 6.3.3 Modifications of the Sone

A modification of the sone scale (Mark VI and subsequently Mark VII sones) was proposed by Stevens (1972) to account for the fact that most real sounds are more complex than pure tones. Utilizing the general form equation (22) below, this method incorporates octave-band, 1/2-octave band, or 1/3-octave band noise measurements and adds to the sone value of the most intense frequency band a fractional portion of the sum of the sone values of the other bands ($\sum S$):

$$\text{Loudness (sones)} = S_m + k\left(\sum S - S_m\right) \qquad (22)$$

where $S_m$ is the maximum sone value in any band, $k$ is a fractional multiplier that varies with bandwidth (octave, $k = 0.3$; 1/2-octave, $k = 0.2$; 1/3-octave, $k = 0.15$), and $\sum S$ is the sum of the sone values of the other bands.

### 6.3.4 Zwicker's Method of Loudness

The concept of the critical band for loudness formed the basis for Zwicker's (1960) method of loudness quantification. The critical band is the frequency band within which the loudness of a band of continuously distributed sound of equal SPL is independent of the width of the band. The critical bands widen as frequency increases. A graphical method is used for computing the loudness of a complex sound based on critical band results obtained and graphed by Zwicker. The noise spectrum is plotted and lines are drawn to depict the spread of a masking effect. The result is a bounded area on the graph which is proportional to total loudness. The method is relatively complex, and Zwicker (1960) should be consulted for computational detail.

### 6.3.5 Noisiness Units

As descriptive terms, *noisiness* and *loudness* are related but not synonymous. Noisiness can be defined as the "subjective unwantedness" of a sound. Perceived noisiness may be influenced by a sound's loudness, tonality,

duration, impulsiveness, and variability (Kryter, 1994). Whereas a low level of loudness might be perceived as enjoyable or pleasing, a low level of unwantedness (i.e., noisiness) is by definition undesirable. Equal-noisiness contours, analogous to equal-loudness contours, have been developed based on a unit (analogous to the phon) called the *perceived noise level* ($\text{PN}_{\text{dB}}$), which is the SPL in decibels of a 1/3-octave band of random noise centered at 1000 Hz, which sounds equally noisy to the sound in question. Also, an N (later D) SLM weighting curve was developed for measuring the perceived noise level of a sound. A subjective noisiness unit analogous to the sone, the *noy*, is used for comparing sounds as to their relative noisiness. One noy is equal to 40 $\text{PN}_{\text{dB}}$, and 2 noys are twice as noisy as 1 noy, 5 noys are five times as noisy, and so on. Similar to the behavior of sones as discussed above for loudness, an increase of about 10 $\text{PN}_{\text{dB}}$ is equivalent to a doubling of the perceived noisiness of a sound.

## 7 SIGNAL DETECTION AND SPEECH COMMUNICATIONS IN NOISE

### 7.1 General Concepts in Signal and Speech Audibility

#### 7.1.1 Signal-to-Noise Ratio Influence

One of the most noticeable effects of noise is its interference with speech communications and the hearing of nonverbal signals. Operators often complain that they must shout to be heard and that they cannot hear others trying to communicate with them. Similarly, noise interferes with the detection of signals such as alarms for general area evacuation and warnings in buildings, annunciators, on-equipment alarms, and machine-related sounds which are relied upon for feedback to industrial workers. In a car or truck, the hearing of external signals, such as emergency vehicle sirens or train horns or in-vehicle warning alarms or messages, may be compromised by the ambient noise levels. The ratio (actually the signed algebraic difference) of the speech or signal level to the noise level, termed the *signal (or speech)-to-noise ratio* (S/N), is a critical parameter in determining whether speech or signals will be heard in noise. A S/N value of +5 dB means that the signal is 5 dB greater than the noise; a S/N value of −5 dB means that the signal is 5 dB lower than the noise.

#### 7.1.2 Masking and Masked Threshold

Technically, *masking* is defined as the increase (in decibels) of the threshold of a desired signal or speech (the *masked sound*) to be raised in the presence of an interfering sound (the *masking sound* or *masker*). For example, in the presence of noisy traffic alongside a busy street, an auditory pedestrian crossing signal's volume must be sufficiently higher than the traffic noise level to enable a pedestrian to hear it, whereas a lower volume will be audible (and possibly more comfortable) when no traffic is present. It is also possible for one signal to mask another signal if both are active at the same time. The *masked threshold* is often defined

in psychophysical terms as the SPL required for 75% correct detection of a signal when that signal is presented in a two-interval task wherein, on a random basis, one of the two intervals of each task trial contains the signal and the noise and the other contains only noise. In a controlled laboratory test scenario, a signal that is about 6 dB above the masked threshold will result in nearly perfect detection performance (Sorkin, 1987). In the remainder of this chapter, various aspects of the masking phenomenon are discussed and methods for calculating a masked signal threshold or, in the case of speech, estimates of intelligibility are presented. Throughout, it is important to remember that the masked threshold is, in fact, a *threshold*; it is *not* the level at which the signal is *clearly* audible. For the ensuing discussion, a functional definition of an auditory threshold is the SPL at which the stimulus is *just audible* to a person listening intently for it in the specified conditions. If the threshold is determined in "silence," as is the case during an audiometric examination, it is referred to as an *absolute threshold*. If, on the other hand, the threshold is determined in the presence of noise, it is referred to as a *masked threshold*.

### 7.2 Analysis of Signal Detectability in Noise

Fundamentally, *detection* of an auditory signal is prerequisite to any other function performed on or about that signal, such as *discrimination* of it from other signals, *identification* of its source, *recognition* of its intended meaning or urgency, *localization* of its placement in azimuth, elevation, and distance, and/or *judgment* of its speed or approach or retreat. Although the S/N ratio is one of the most critical parameters that determine a signal's detectability in a noise, there are many other factors as well. These include the spectral content of the signal and noise (especially in relation to the *critical bandwidth*), temporal characteristics of signal and noise (especially in relation to the contrast between them), duration of the signal's presentation, listener's hearing ability, demands on the listener's attention, criticality of the situation at hand, and the attenuation of hearing protectors, if used. These factors are discussed in detail in Robinson and Casali (2003) and Casali and Gerges (2006). The ensuing discussion concentrates on the most important issue of spectral content of the signal and noise and how that content impacts masking effects on audibility.

#### 7.2.1 Spectral Considerations and Masking

Generally speaking, the greater the decibel level of the background noise relative to the signal (inclusive of speech), the more difficult it will be to hear the signal. Conversely, if the level of the background noise is reduced and/or the level of the signal is increased, the masked signal will be more readily audible. In some cases, ambient noise can be reduced through engineering controls, and in the same or other cases it may be possible to increase the intensity of the signals. Although most off-the-shelf auditory warning devices have a preset output level, it is possible to increase the effective level of the devices by distributing multiple alarms or warning devices throughout a coverage area instead of relying on one centrally located device. This approach can also be used for variable-output systems such as public address loudspeakers since simply increasing the output of such systems often results in distortion of the amplified speech signal, thereby reducing intelligibility. Simply increasing the signal level without adding more sound sources can have the undesirable side effect of increasing the noise exposures of people in the area of the signal if the signal is sounded too often. If the signal levels are extremely high (e.g., over 105 dB), exposed persons could experience temporary threshold shifts or tinnitus if they are in the vicinity of the device when it is sounding. As to a working decibel range for auditory warning signals, a recommendation from the International Organization for Standardization (ISO, 2003) standard "Danger Signals for Public and Work Areas—Auditory Danger Signals" is that the signal shall not be less than 65 dBA or more than 118 dBA in the signal reception area.

One problem directly related to the level of the background noise is distortion within the inner ear. At very high noise levels, the cochlea becomes overloaded and cannot accurately transduce/discriminate different forms of acoustic energy (e.g., signal and noise) reaching it, resulting in the phenomenon known as *cochlear distortion*. In order for a signal, including speech, to be audible at very high noise levels, it must be presented at a higher level, relative to the background noise, than would be necessary at lower noise levels. This is one reason why it is best to make reduction of the background noise a high priority in occupational or other environments.

In addition to manipulating the levels of the auditory displays, alarms, warnings, and background noise, it is also possible to increase the likelihood of detection of an auditory display or alarm by manipulating its spectrum so that it contrasts with the background noise and other common workplace sounds. In a series of experiments, Wilkins and Martin (1982, 1985) found that the contrast of a signal with both the background noise and irrelevant signals was an important parameter in determining the detectability of a signal. For example, in an environment characterized by high-frequency noise such as sawing and/or planing operations in a wood mill, it might be best to select a warning device with strong low-frequency components, perhaps in the range of 500–800 Hz. On the other hand, for low-frequency noise such as might be encountered in the vicinity of large-capacity, slow-rotation ventilation fans, an alarm with strong midfrequency components in the range of 1000–1500 Hz might be a better choice.

***Upward Spread of Masking*** When considering masking of a tonal signal by a tonal noise or a narrow band of noise, masking is greatest in the immediate vicinity of the masking tone or, in the case of a band-limited noise, the center frequency of the band. (This is one reason why increasing the contrast in frequency between the signal and noise can increase the audibility of a signal.) However, the masking effect does spread out above and below this frequency, being greater at the frequencies above the frequency of the masking noise

than at frequencies below the frequency of the masking noise (Wegel and Lane, 1924; Egan and Hake, 1950). This phenomenon, referred to as the *upward spread of masking*, becomes more pronounced as the level of the masking noise increases, probably due to cochlear distortion. In practical situations, masking by pure tones would seldom be a problem, except in instances where the noise contains strong tonal components or if two warnings with similar frequencies were activated simultaneously. Although less pronounced, upward spread of masking does occur when band-limited noises are used as maskers. This phenomenon is illustrated in Figure 10.

***Masking with Broadband Noise*** A very common form of masking characteristic of typical industrial workplaces or building spaces such as conference rooms or auditoria occurs when a signal or speech is masked by a broadband noise. Experiments on broadband noise masking commonly employ white or pink noise. White noise sounds very much like static on a radio tuned to a frequency that is between broadcast channels, and it consists of equal energy by hertz, while pink noise sounds like the roar of a waterfall, consisting of a 3-dB-per-octave decrease in energy as frequency increases in hertz. In examining the masking of pure-tone stimuli by white noise, Hawkins and Stevens (1950) found that masking was directly proportional to the level of the masking noise, irrespective of the frequency of the

masked tone. In other words, if a given background white noise level increased the threshold of a 2500-Hz tone by 35 dB, the threshold of a 1000-Hz tone would also be increased by 35 dB. Furthermore, they found that for the noise levels investigated masking increased linearly with the level of the white noise, meaning that if the level of the masking noise were increased 10 dB, the masked thresholds of the tones also increased by 10 dB. The bottom line is that broadband noise such as white or pink noise, due to its inclusion of all frequencies, serves as a very effective masker of tonal signals and speech. Thus, its abatement often needs to be of high priority. On the other hand, white or pink noises may be useful as in intentional maskers to mask the distractions created by conversations and phone ringers among open-plan offices, although it is debatable whether one noise should be added to combat another noise in this sense.

### 7.2.2 Signal Audibility Analysis Method Based on Critical Band Masking

Fletcher (1940) developed what would become *critical band theory*, which has formed the fundamental basis for explaining how signals are masked by narrowband noise. According to this theory, the ear behaves as if it contains a series of overlapping auditory filters, with the bandwidth of each filter being proportional to its center frequency. When masking of pure tones by broadband noise is considered, only a narrow "critical band" of the noise centered at the frequency of the tone is effective as

**Figure 10** Upward spread of masking of a pure tone by three levels (40, 60, and 80 dB) of a 90-Hz-wide band of noise centered at 410 Hz. The ordinate (*y* axis) is the amount (in decibels) by which the absolute threshold of the masked tone is raised by the masking noise, and the abscissa is the frequency of the masked tone. (Adapted with permission from Egan and Hake, 1950.)

a masker and the width of the band is dependent only on the frequency of the tone being masked. In other words, the masked threshold of a pure tone could be predicted simply by knowing the frequency of the tone and the spectrum level (decibels per hertz) of the masking noise, assuming that the noise spectrum is reasonably flat in the region around the tone. Thus, the masked threshold of a tone in white noise would simply be

$$L_{mt} = L_{ps} + 10 \log (BW) \qquad (23)$$

where $L_{mt}$ is the masked threshold, $L_{ps}$ is the spectrum level of the masking noise, and BW is the width of the auditory filter centered around the tone. Strictly speaking, this relationship applies only when the masking noise is flat (equal energy by hertz) and when the masked signal has a duration greater than 0.1 s. However, an acceptable approximation may be obtained for other noise conditions as long as the spectrum level in the critical band does not vary by more than 6 dB (Sorkin, 1987). In many environments, the background noise is likely to be sufficiently constant and can often be presumed to be flat in the critical band for a given signal. The exception to this assumption is a situation where the noise has prominent tonal components and/or fluctuates a great deal.

The spectrum level of the noise in each of the 1/3-octave bands containing the signal components *is not* the same as the band level measured using an octave-band or 1/3-octave-band analyzer. Spectrum level refers to the level per hertz, or the level that would be measured if the noise were measured using a filter that is 1 Hz wide. If it is assumed that the noise is flat within the bandwidth of the 1/3-octave-band filter, the spectrum level can be estimated using the equation

$$L_{ps} = 10 \log (10^{L_{pb}/10}/BW_{1/3}) \qquad (24)$$

where $L_{ps}$ is the spectrum level of the noise within the 1/3-octave band, $L_{pb}$ is the SPL measured in the 1/3-octave band in question, and $BW_{1/3}$ is the bandwidth of the 1/3-octave band, calculated by multiplying the center frequency ($f_c$) of the band by 0.232.

Finally, the bandwidth of the auditory filter can be approximated by multiplying the frequency of the masked signal/tone by 0.15 (Patterson, 1982; Sorkin, 1987). If the signal levels measured in one or more of the 1/3-octave bands considered exceed these masked threshold levels, the signal should be audible. A computational example using the critical band method appears in Robinson and Casali (2003).

### 7.2.3 Signal Audibility Analysis Method Based on ISO Standard 7731-2003(E)

The Department of Defense, National Fire Protection Association, Society of Automotive Engineers, Underwriters' Laboratories, ANSI, and ISO are examples of organizations that have promulgated standards to guide the design of auditory warning signals for specific applications, such as on-vehicle warnings, sirens,

on-firefighter alarms, evacuation alarms, and fire alarms. However, for performing an *analysis* of most any acoustic alarm as to its predicted audibility in a specific noise, perhaps the most comprehensive standard is ISO 7731-2003(E), "Danger Signals for Public and Work Areas—Auditory Danger Signals" (ISO, 2003). (This standard provides guidelines for calculation of the masked threshold of audibility but also specifies the spectral content and minimum signal-to-noise ratios (S/N) of the signals and requires special considerations for people suffering from hearing loss or those wearing HPDs.)

Application of ISO 7731 (2003) is best illustrated by an example. A warning signal that is quite common is a standard backup alarm typically found on commercial trucks and construction/industrial equipment. It has strong tonal components in the range 1000–2000 Hz and significant harmonic components at higher frequencies (Casali and Alali, 2009). The alarm has a 1-s period and a 50% duty cycle (i.e., it is "on" for 50% of its period). The levels in all other 1/3-octave bands are sufficiently below those in the bands mentioned as to be inconsequential. The levels needed for audibility of this signal will be determined for application in a hypothetical masking noise spectrum represented by its 1/3-octave and octave band levels, shown in columns 2 and 4, respectively, in Table 1.

1.  Starting at the lowest octave-band or 1/3-octave-band level available, the masked threshold ($L_{mt1}$) for a signal in that band is

$$L_{mt1} = L_{pb1} \qquad (25)$$

where $L_{pb1}$ is the SPL measured in the octave band or 1/3-octave band in question.

2.  For each successive octave-band or 1/3-octave-band filter $n$, the masked threshold ($L_{mtn}$) is the noise level in that band or the masked threshold in the preceding band less a constant, whichever is *greater*:

$$L_{mtn} = \max(L_{pbn}; L_{mtn-1} - C) \qquad (26)$$

where $C$ equals 7.5 dB for octave-band data or 2.5 dB for 1/3-octave-band data.

For an auditory signal to be *"clearly audible,"* ISO 7731 requires that at least one of the following be met: (1) the dBA level of the signal must exceed the dBA level of the ambient noise by more than 15 dB, (2) the signal level must exceed the masked threshold by at least 10 dB in at least one octave band, or (3) the signal level must exceed the masked threshold by at least 13 dB in at least one 1/3-octave band. Furthermore, the spectral content of the signal must include frequency components in the range of 500–2500 Hz, and it is recommended that there be two dominant components in the subset range of 500–1500 Hz. Furthermore, to accommodate persons with hearing loss or using hearing protection, "sufficient" signal energy below 1500 Hz is recommended.

**Table 1  Masked Threshold Calculations according to ISO 7731-2003(E) for 1/3-Octave-Band and Octave-Band Methods**

| (1) Center Frequency (Hz)[a] | (2) $\frac{1}{3}$-Octave-Band Level (dB) | (3) Masked Threshold (dB)[b] | (4) Octave-Band Level (dB) | (5) Masked Threshold (dB)[b] |

[a]Frequencies in boldface type are octave-band center frequencies.
[b]Thresholds in boldface type are the masked thresholds for the signal components of the backup alarm described in the text.

While the aforementioned broadband dBA measurement is sufficient per ISO 7731, the 1/3-octave band or full-octave band procedures which are computed by equations (25) and (26) and exemplified by the data in Table 1 are preferred, due to their higher spectral precision. These procedures (unlike the aforementioned critical band procedure) presume that the auditory filter

width is equal to the 1/3-octave band or to the octave band and also takes upward spread of masking into account by comparing the level in the band in question to the level in the preceding band. For example, for the 1250-Hz row of column 3, it can be seen that the masked threshold of the previous 1/3-octave band (1000 Hz) determines, via equation (26), the masked threshold (77.1 dB) of the 1250-Hz band due to upward masking effects. The masked thresholds for each 1/3-octave band and octave band of noise for the example are shown in columns 3 and 5, respectively, in Table 1. For the purposes of the example signal (a backup alarm), only the thresholds for the 1/3-octave bands centered at 1000, 1250, 2000, and 2500 Hz and the threshold for the octave bands centered at 1000 and 2000 Hz are relevant, because these are the signal's dominant component bands, and they overlap the standard's spectral requirements noted above. (But if the signal had possessed significant energy below 1000 Hz, then the 1/3-octave bands centered at 500, 630, and 800 Hz would require attention, as would the octave band centered at 500 Hz.)

The conclusion is that if the signal levels measured in one or more of these bands exceed the calculated masked threshold levels (as indicated by boldface type), then the backup alarm is predicted to be *barely audible.* More importantly, to next determine the necessary sound level output of the alarm to render it "clearly audible" per ISO 7731, to simplify we will assume that the backup alarm's dominant frequency bands (1000, 1250, 2000, and 2500 Hz) themselves cannot change but their decibel output can be raised. Thus, based on the 1/3-octave analysis, in order for the alarm to be reliably audible, *the signal level would have to be at least the following in at least one of these four 1/3-octave bands*: centered at 1000 Hz: $79.6 + 13 = 92.6$ dB; at 1250 Hz: $77.1 + 13 = 90.1$ dB; at 2000 Hz: $80.1 + 13 = 93.1$ dB; at 2500 Hz: $85.3 + 13 = 98.3$ dB. Or, based on the octave analysis, in order for the alarm to be reliably audible, *the signal level would have to be at least the following in at least one of these two octave bands*: centered at 1000 Hz: $81.5 + 10 = 91.5$ dB; at 2000 Hz: $87.9 + 10 = 97.9$ dB. Of course, these results are based on ISO 7731's criteria for *clear audibility* and are well above the levels required for threshold audibility.

The ISO 7731 (2003) standard provides a procedure which may be used to calculate masked thresholds with and without HPDs. Calculating a protected masked threshold for a particular signal requires (1) subtracting the attenuation of the HPD from the noise spectrum to obtain the noise spectrum effective when the HPD is worn; (2) calculation of a masked threshold for each signal component using the procedures outlined in the preceding discussion, which results in the signal component levels that would be *just audible* to the listener when the HPD is worn; and (3) adding the attenuation of the HPD to the signal component thresholds to provide an estimate of the environmental (exterior to the HPD) signal component levels that would be required to produce the under-HPD threshold levels calculated in step 2. Although not difficult, this procedure does

require a reasonably reliable estimate of the actual attenuation provided by the HPD. The manufacturer's data supplied with the HPD are unsuitable for this purpose because they overestimate the real-world performance of the HPD, as explained in Section 4.2.3. Furthermore, if a 1/3-octave band masking computation is desired, the manufacturer's attenuation data, which are available for only nine selected 1/3-octave bands, are insufficient for the computation. Finally, the standard does not take the listener's hearing level into account. It is simply assumed that if the calculated masked thresholds are above the listeners' absolute thresholds, the signals should be audible, and if hearing impairment is at issue, signals should include sufficient energy below 1500 Hz.

As alluded to previously, use of the ISO 7731 standard for prediction of masked threshold for auditory signals is not limited to the octave and 1/3-octave calculations discussed herein, although the latter is the most precise method. As a less precise method (which is advocated by this author only as a last resort), ISO 7731 also offers a broadband analysis that can be performed by obtaining the dBA level of the ambient noise, and if the signal exceeds this level by 15 dB, it is said to be audible in most circumstances. However, this does not take into account upward masking or other spectrally specific effects, and it may result in (unnecessarily) higher signal levels than computed by either spectral technique. ISO 7731 also includes recommendations for signal temporal characteristics with repetition rates of 0.5–4 Hz, unambiguous meaning, discriminability, and addition of redundant visual signals if the ambient noise exceeds 100 dBA.

The broadband S/N recommendation of 15 dB of ISO 7731 is generally in keeping with those of auditory researchers. For example, Sorkin (1987) suggests that signal levels 6–10 dB above masked threshold are adequate to ensure 100% detectability, whereas signals which are approximately 15 dB above their masked threshold will elicit rapid operator response. He also suggests that signals more than 30 dB above the masked threshold could result in an unwanted startle response and that no signal should exceed 115 dB. [This suggested the upper limit on signal level is consistent with OSHA hearing conservation requirements (OSHA, 1983), which prohibits exposure to continuous noise levels greater than 115 dBA.] These recommendations are in line with those of other authors (Deatherage, 1972; Wilkins and Martin, 1982).

Masked thresholds estimated via ISO 7731 are not necessarily exact, nor are they intended to be. The "clearly audible" design estimates represent conservative estimates for a large segment of the population representing a wide range of hearing levels for nonspecific noise environments and signals. Further information on the design of auditory warnings and alarms, including relevant technical standards and guidelines, appears in Robinson and Casali (2003). Before embarking on the design of any auditory signal that is associated with a safety issue, the designer should first determine if there are any standards or regulations that have bearing. In this area of acoustics, the coverage of consensus standards is fairly broad and in depth.

## 7.3 Analysis of Speech Intelligibility in Noise

Many of the concepts presented above that relate to the masking of nonspeech signals by noise apply equally well to the masking of speech, so they will not be repeated in this section. However, for the spoken message, the concern is not simply audibility or detection but, rather, intelligibility. The listener must understand *what* was said, not simply know that something was said. Furthermore, speech is a very complex broadband signal whose components are not only differentially susceptible to noise but also highly dependent on vocal effort, the gender of the speaker, and the content and context of the message. In addition, other factors must be considered, such as the effects of HPD use by the speaker and/or listener, hearing loss of the listener, or speech signal degradation occurring in a communications system.

### 7.3.1 Speech-to-Noise Ratio Influence

Similar to the case with nonverbal signals, the signed difference between the speech level and the background noise level is referred to as the *speech-to-noise* (S/N) *ratio*. The speech level referred to is usually the long-term rms level measured in decibels. When background noise levels are between 35 and 110 dB, an S/N ratio of 12 dB is usually adequate to reach a normal-hearing person's threshold of intelligibility (Sanders and McCormick, 1993); however, it is quite impossible for anyone to sustain the vocal efforts required in the higher noise levels without electronic amplification (i.e., a public address system). The *threshold of intelligibility* is defined as the level at which the listener is just able to obtain without perceptible effort the meaning of almost every sentence and phrase of continuous speech (Hawkins and Stevens, 1950, p. 11); essentially, this is 100% intelligibility. Intelligibility decreases as S/N decreases, reaching 70–75% (as measured using phonetically balanced words) at an S/N of 5 dB, 45–50% at an S/N of 0 dB, and 25–30% at an S/N of −5 dB (Acton, 1970).

At least in low to moderate noise levels, people seem to modulate their vocal effort automatically, using the *Lombard reflex*, to maintain S/N ratios in increasing background noise so that they can communicate with other people. However, there is an upper limit to this ability, and speech levels cannot be maintained at more than 90 dB for long periods (Kryter, 1994). Since a relatively high S/N ratio (12 dB or so) is necessary for reliable speech communications in noise, it should be obvious that in high noise levels (greater than about 75–80 dB), unaided speech cannot be relied upon except for short durations over short distances. Furthermore, since speech levels for females tend to be about 2–7 dB less than for males, depending on vocal effort, the female voice is at a disadvantage in high levels of background noise.

An additional factor which impinges on the amplitude modulation of one's own voice is that of the *occlusion effect* (Stenfelt and Reinfeldt, 2005; Casali, 2010a), which results when the ear canal is occluded, as with an earplug for hearing protection or with a custom-molded,

in-the-ear hearing aid. The occlusion effect results from an enhancement of internal bodily conduction of sound that is caused by occlusion of the ear canal and its resultant attenuation of the air conduction pathway, as compared to that which occurs with the open ear where both air conduction and bone conduction feedback are present (Stenfelt and Reinfeldt, 2005). Compared to one's own voice levels in the canal of an open ear, measurably higher SPLs result within an occluded canal; therefore, the auditory feedback to the occluded person is that his or her own voice sounds louder than with a normally open canal, and this affects amplitude modulation during vocal utterances. Therefore, the speech output is generally lower in level when the ear canal is occluded, the opposite of the desired effect when the speaker is in noise, as is usually the case with hearing protection. The effect is maximized as the entrapped volume of the ear canal is at its largest, such as with a shallowly inserted earplug, and in addition to making one's own voice sound louder, it often renders the voice as sounding like it has more bass and resonance. Also, sounds of bodily origin, such as breathing and footfalls, are heard as unnaturally loud (Casali, 2010a). This can cause particular problems for soldiers who may be wearing shallow-insertion, passive earplugs and who are trying to whisper and otherwise maintain covert operations.

### 7.3.2 Speech Bandwidth Influence

The speech bandwidth extends from 200 to 8000 Hz, with male voices generally having more energy than female voices at the low frequencies (Kryter, 1974); however, the region between 600 and 4000 Hz is most critical to intelligibility (Sanders and McCormick, 1993). This also happens to be the frequency range at which most auditory alarms are presented, providing an opportunity for the direct masking of speech by an alarm or warning. Therefore, speech communications in the vicinity of an activated alarm can be difficult.

Consonant sounds, which are generally higher than vowel sounds in the 600–4000 Hz bandwidth, are also more critical than vowels to intelligibility. This fact renders speech differentially susceptible to masking by band-limited noise, depending on the level of the noise. At low levels, bands of noise in the mid- to high-frequency ranges mask consonant sounds directly, thus impairing speech intelligibility more than would low-frequency sounds presented at similar levels. However, at high levels, low-frequency bands of noise can also adversely affect intelligibility due to upward spread of masking into the critical speech bandwidth.

When electronic transmission/amplification systems are used to overcome problems associated with speech intelligibility, it is important to understand that the systems themselves may exacerbate the problem if they are not designed properly. Most industrial telecommunications systems [i.e., intercoms, telephones, personal assistant (PA) systems] do not transmit the full speech bandwidth, nor do they reproduce the entire dynamic range of the human voice. To reduce costs and simplify the electronics, such systems often filter the signal and pass (transmit) only a portion of the speech bandwidth (e.g., the telephone passband is generally 300–3600

Hz). If the frequencies above 4000 Hz or the frequencies below 600 Hz are filtered out (not transmitted), there is little negative impact on speech intelligibility, even though the voice may not appear as natural or as pleasing as when its full bandwidth is available. However, if the frequencies between 1000 and 3000 Hz are filtered out of the signal, intelligibility is severely impaired (French and Steinberg, 1947).

In addition to filtering the speech signal, it is possible to clip the speech peaks so that the full dynamic range of a speaker's voice is not transmitted to a listener. This clipping may be intentional on the part of the designer to reduce the cost of the system or it may be an artifact of the amplitude distortion caused by an overloaded amplifier. Either way, the effects on intelligibility are the same. Since the speech peaks contain primarily vowel sounds and intelligibility relies predominantly on the recognition of consonants, there is little loss in intelligibility due strictly to peak clipping. However, if the clipping is caused by distortion within the amplifier, there may be ancillary distortion of the speech signal in other ways that could affect intelligibility adversely.

### 7.3.3 Acoustic Environment Influence

The acoustic environment (room volume, distances, barriers, reverberation, etc.) can also have a dramatic effect on speech intelligibility. This is a complex subject in sound propagation and architectural acoustics, and a detailed treatment is beyond the scope of this chapter, but more information may be found in Kryter (1974, 1994) and Harris (1991). One fairly obvious point is that as the distance between the listener and the speech source (person or loudspeaker) increases, the ability to understand the speech can be affected adversely if the S/N ratio decreases sufficiently. In the same vein, barriers in the source–receiver path can create shadow zones in which the S/N ratio is insufficient for reliable intelligibility. Finally, speech intelligibility decreases linearly as reverberation time increases. Reverberation time ($RT_{60}$) is defined for a given space as the time (in seconds) required for a steady sound to decay by 60 dB from its original value after being shut off. Each 1-s increase in reverberation time will result in a loss of approximately 5% in intelligibility (Fletcher, 1953). Thus, rooms with long reverberation times, producing an echo effect, will not provide good conditions for speech reception.

### 7.3.4 Speech Intelligibility Analysis Method Based on the Preferred Speech Interference Level

There are a number of techniques to analyze or in some cases to predict accurately the intelligibility of a speech communications system based on empirical measurements of an incident noise and, in some cases, additional measurements of the system's speech output, be it amplified or live unamplified voice. A variety of techniques are covered in Sanders and McCormick (1993) and Kryter (1994). However, one of the better known techniques, the preferred speech interference level (PSIL), which involves only measurements of the noise and is straightforward to administer (although limited in its predictive ability), warrants discussion here.
**Figure 11** Relationship among PSIL, speech difficulty, vocal effort, and speaker–listener separation. (Adapted with permission from Sanders and McCormick, 1993.)

The PSIL is the arithmetic average of the noise levels measured in three octave bands centered at 500, 1000, and 2000 Hz (Peterson and Gross, 1978). It is most useful when the spectrum of the background noise is relatively flat and intended only as an indication of whether or not there is likely to be a communications problem, not as a predictor of intelligibility. If the background noise is not flat, is predominated by or contains strong tonal components, or fluctuates a great deal, the utility of the PSIL is lessened. As an example of PSIL application, the hypothetical octave-band noise spectrum presented earlier in column 4 of Table 1 can be used. The PSIL for this spectrum is $(80.7 + 81.5 + 87.9)/3 = 83$. With this information, Figure 11 can be consulted to determine how difficult verbal communication is likely to be in this noise. At a PSIL of 83, verbal communications will be "difficult" at any speaker–listener distance greater than about 18 in. Even at closer distances, a "raised" or "very loud" voice must be used. If octave-band levels are not available, the A-weighted sound level may also provide rough guidance concerning the speech-interfering effects of background noise, also shown in Figure 11. In summary, the PSIL is a useful, simple tool for estimating the degree of difficulty that can be expected when verbal communications are attempted in a steady, flat background noise.

### 7.3.5 Speech Intelligibility Analysis Method Based on the Speech Intelligibility Index (SII) and Extended SII

In contrast to the PSIL, a more precise analytical prediction of the interfering effects of noise on speech communications may be conducted using the speech intelligibility index (SII) technique defined in ANSI S3.5-1997(R2007) (ANSI, 2007b). Essentially, this well-known standardized technique utilizes a weighted sum of the S/N ratios in specified frequency bands to compute an SII score ranging between 0.0 and 1.0, with higher scores indicative of greater predicted speech intelligibility. While the end result is an SII score on a simple scale or 0.0–1.0, the process of measurement and calculation is complex by comparison to the PSIL. However, the SII is more accurate than the PSIL, broader in its coverage, and can account for many additional factors, such as speaker vocal effort, room reverberation, monaural versus binaural listening, hearing loss, varying message content, hearing protector effects, communications system gain, and the existence of external masking noise.

Four calculation methods are available with the SII: the critical band method (most accurate), the 1/3-octave-band method, the equally contributing critical band method, and the octave-band method (least accurate) (ANSI, 2007b). At a minimum, the calculations require knowledge of the spectrum level of the speech and noise as well as the listeners' hearing thresholds. Where speech spectrum level(s) are unavailable or unknown, the standard offers guidance in their estimation. Although quite flexible in the number and types of conditions to which it can be applied, application of the standard is limited to natural speech, otologically normal listeners with no linguistic or cognitive deficiencies, and situations that do not include sharply filtered bands of speech or noise. Software programs for calculation of the SII may be obtained at http://www.sii.to/html/programs.html.

The SII "score" actually represents the proportion of the speech cues that would be available to the listener for "average speech" under the noise/speech conditions for which the calculations were performed. Hence, intelligibility is predicted to be greatest when the SII = 1.0, indicating that all of the speech cues are reaching the listener, and poorest when the SII = 0.0, indicating that none of the speech cues are reaching the listener. The general steps used in calculating the SII and estimating intelligibility are beyond the scope of this chapter, but

they may be found in the standard itself, ANSI S3.5-1997(R2007) (ANSI, 2007b), or in paraphrased terms with examples in Robinson and Casali (2003).

A limitation of the SII model is that it employs a long term speech and noise spectrum and thus was designed and validated for masking noises that are stationary, that is, invariant over time. However, in fluctuating noises, speech intelligibility for the normal hearer may be different, and often better, than that in stationary noises because the listener can benefit from the relatively quiet periods in the noise. In an effort to extend the SII model to accommodate nonstationary noises, Rhebergen and others (e.g., Rhebergen et al., 2006) developed and have recently been involved in validating the Extended SII. The basic principle is that the system's speech output and its noise environment are partitioned into segments or time frames over the time course of the speech presentation. Within each frame, the SII is calculated to provide an instantaneous value; next, the instantaneous SII values are averaged to produce an SII for that particular speech-in-noise condition (Rhebergen et al., 2006). Extant data for these metrics indicate that the extended SII provides accurate predictions for a variety of time-variant noise conditions; however, more validation and refinements were underway as of the publication date of this chapter. This method demonstrates promise for prediction of speech reception thresholds in fluctuating noise (which is a common masking situation), thus adding practical value to the utility of the SII that is standardized in ANSI S3.5-1997(R2007) (ANSI, 2007b).

### 7.3.6 Speech Intelligibility Experimental Test Methods

In lieu of analytical techniques such as the PSIL and the SII, both of which require spectral measurements, an alternative (or complementary) approach is to conduct an experiment to measure intelligibility for a given set of conditions with a group of human listeners. For this purpose, there exists a standard, ANSI S3.2-1989(R2009), which provides not only guidance for conducting such tests but also three alternative sets of standard speech stimuli (ANSI, 2009). The standard is intended for designers and manufacturers of communications systems and provides valuable insight into the subject of speech intelligibility and how various factors associated with the speaker, transmission path/environment, and listener can affect it. The standard accommodates empirical testing of intelligibility in the following situations: indoors or outdoors, speaking face to face or in vicinity, telephonic systems, public address systems, radio systems, and complex systems that include air, wire, wireless, fiber optics, and water transmission paths that are applied in certain military, remote, or emergency systems. Thus, ANSI S3.2-1989(R2009) can be of benefit to the human factors designers/evaluators of many types of communications systems when empirical measurement of speech intelligibility performance is necessary for evaluation, acceptance, or proving efforts.

Although space does not permit a detailed description of the procedures, the ANSI S3.2 standard's strategy involves presenting speech stimuli to a listener in an environment that replicates the conditions of concern and measuring how much of the speech message is understood. The speech stimuli may be produced by a trained talker speaking directly to the listener while in the same environment or via an intercom system. Alternatively, the materials may be recorded and presented electronically. Use of recorded stimuli and/or electronic presentation of the stimuli offers the greatest control over the speech levels presented to the listener.

### 7.4 Other Considerations for Signal Detectability and Speech Intelligibility

#### 7.4.1 Distance Effects

It cannot be overemphasized that the noise and signal levels referred to in the analysis techniques above refer to the levels measured *at the listener's location*. Measurement made at some central location or the specified output levels of the alarm or warning devices are not representative of the levels present at a given workstation and cannot be used for masked threshold calculations. In a free-field, isotropic environment, the sound level of an alarm or warning will decrease in inverse relationship to the distance from the source, in accordance with the formula

$$p_1/p_2 = d_2/d_1 \qquad (27)$$

where $p_1$ and $p_2$ are the sound pressures of the signal at distances $d_1$ and $d_2$, respectively, in micropascals or dynes per square centimeters and $d_1$ and $d_2$ are, respectively, distance 1 (near point) and distance 2 (far point) at which the signal is measured, in linear distance units, or, alternatively, where the drop between distance 1 and 2 in the SPL of the signal in decibels is given by

$$\text{SPL}_{\text{drop}} = 20 \log_{10}(d_2/d_1) \qquad (28)$$

These formulas provide accurate results in outdoor environments where there are no barriers, such as trees, or highly reflecting planes, such as paved parking lots. Indoors, the formulas will typically overestimate the drop in signal level, where reflective surfaces reinforce the signal as it propagates.

#### 7.4.2 Barrier Effects

Furthermore, buildings or other large structures in the source–receiver path can create "shadow zones" in which little or no sound is audible. It is for these reasons that the U.S. Department of Defense (1981) recommends that frequencies below 1000 Hz be used for outdoor alarms since low frequencies are less susceptible to atmospheric absorption and diffract more readily around barriers. Similar problems can be encountered indoors as well. Problems associated with the general decrease in SPL with increasing distance as well as shadow zones created by walls, partitions, screens, and machinery/vehicles must be considered. Since different materials reflect and absorb sound depending on its frequency, not only do the sound levels change from position to position, but the spectra of both the noise and signals/speech can change as well. Finally,

since most interior spaces reverberate to some degree, the designer should also be concerned with phase differences between reflected sounds, which can result in superposition effects of enhancement or cancellation of the signals and speech from location to location. It is for all these reasons that it is necessary to know the SPL at the *listener's location* when considering masked thresholds.

### 7.4.3  Hearing Protection Device Effects

HPDs are often blamed for exacerbating the effects of noise on the audibility of speech and signals, although, at least for people with normal hearing, protectors may actually facilitate hearing in some noisy situations. Overall, the research evidence on normal hearers generally suggests that *conventional* passive HPDs have little or no degrading effect on the wearer's under-standing of external speech and signals in ambient noise levels above about 80 dBA and may even yield some improvements, with a crossover between disadvantage and advantage between 80 and 90 dBA. However, HPDs do often cause increased misunderstanding and poorer detection (compared to unprotected conditions) in lower sound levels, where HPDs are not typically needed for hearing defense anyway but may be applied for reduction of annoyance (Casali and Gerges, 2006). In intermittent noise, HPDs may be worn during quiet periods so that when a loud noise occurs, the wearer will be protected. However, during those quiet periods, the conventional passive HPDs typically reduce hearing acuity. In certain of these cases, the family of *amplitude-sensitive augmented HPDs* may be benefi-cial, including those that provide, during quiet periods, minimal or moderate passive attenuation via acoustic valving systems (or, alternatively, more amplification of external sounds via electronically-modulated sound transmission through the HPD) but then also provide increased passive attenuation (or less amplification) as the incident noise increases. However, the real performance effects of these and other augmented HPDs are very situation-specific, and the interested reader is pointed to the reviews in Casali (2010a,b).

Noise- and age-induced hearing losses generally occur in the high-frequency regions first, and for those so impaired, the effects of HPDs on speech perception and signal detection are not clear-cut. Due to their already elevated thresholds for mid- to high-frequency speech sounds being raised further by the protector, hearing-impaired persons are usually disadvantaged in their hearing by conventional HPDs. Although there is no consensus across studies, certain reviews have con-cluded that sufficiently hearing-impaired persons will usually experience additional reductions in communica-tions abilities with conventional HPDs worn in noise. In some instances, HPDs with electronic hearing-assistive circuits, sometimes called *sound-transmission or sound restoration HPDs*, can be offered to hearing-impaired persons to determine if their hearing, especially in quiet to moderate noise levels below about 85 dBA, may be improved with such devices while still receiving a measure of protection. However, as noted above, the realized benefits of such devices are very dependent

upon the particular signal-in-noise situation as well as the individual's particular hearing loss (Casali, 2010a,b).

Conventional passive HPDs cannot differentiate or selectively pass speech or nonverbal signal (or speech) energy versus noise energy at a given frequency. Therefore, conventional HPDs do not improve the S/N ratio in a given frequency band, which is the most important factor for achieving reliable signal detection or intelligibility. Conventional HPDs attenuate high-frequency sound more than low-frequency sound, thereby attenuating the power of consonant sounds that are important for word discrimination as well as most warning signals, both of which lie in the higher frequency range, while also allowing low-frequency noise through. Thus, the HPD may enable an associated upward spread of masking to occur if the penetrating noise levels are high enough. Certain augmented HPD technologies help to overcome the weaknesses of conventional HPDs as to low-frequency attenuation in particular; these include the aforementioned *active noise reduction* (ANR) devices, which via electronic phase-derived cancellation of noises below about 1000 Hz improve the low-frequency attenuation of passive HPDs. Concomitant benefits of ANR-based HPDs can include the reduction of upward spread of masking of low-frequency noise into the speech and warning signal bandwidths, as well as reduction of noise annoyance in certain environments that are dominated by low frequencies, such as jet aircraft cockpits and passenger cabins (Casali et al., 2004; Casali, 2010b).

In any case, by far the most commonly applied HPDs are relatively simple, conventional products for which the paramount objective is the passive attenuation of noise and thus the prevention of noise-induced hearing loss. However, as noted throughout this chapter, there are many workplace, military, and leisure situations wherein noise may be a hazard to the ears, but there also exists a critical need to hear external signals and/or speech and, in general, to maintain one's situation awareness. It is for these reasons that more design team efforts, combining the expertise of human factors engineers with those of acousticians and audiologists, need to be aimed directly at improving hearing pro-tector capabilities for signal detection, identification, localization, and communications along with providing ample protective effectiveness against noise hazards.

### 7.4.4  Hearing-Aided Users

People with a hearing loss sufficient to require the use of hearing aids are already at a disadvantage when attempting to hear auditory alarms, warnings, or speech, and this disadvantage is exacerbated when noise levels are high. Activation of hearing aids in high levels of noise so as to improve hearing of speech or signals can increase the risk of additional damage to hearing due to amplification of the ambient noise (Humes and Bess, 1981). But shutting off the hearing aids increases the chance that the signals will be missed, and since it has been shown that vented hearing aid inserts do not function well as hearing protectors (Berger, 2003b), there is still a risk of further hearing damage by doing so. Recommendations for accommodating hearing-aided

users in the workplace appear in Robinson and Casali (2003).

## 7.5 Summary of Guidance for Reducing Effects of Noise on Signals and Speech

The following principles regarding masking effects on nonverbal signals and speech are offered as a summary for general guidance:

1. Due to *direct masking*, the greatest increase in masked threshold occurs for nonverbal signal frequencies that are equal or near the predominant frequencies of the masking noise. Therefore, warning signals should not utilize tonal frequencies equivalent to those of the masker. Preferably, the signal should contain energy in the most sensitive range of human hearing, approximately 1000–4000 Hz, unless the noise energy is intense at these frequencies.

2. If the signal and masker are tonal in nature, the primary masking effect is at the fundamental frequency of the masker and at its harmonics. For instance, if a masking noise has primary frequency content at 1000 Hz, this frequency and its harmonics (2000, 3000, 4000, etc.) should be avoided as signal frequencies.

3. The greater the SPL of the masker, the more the increase in masked threshold of the signal. A general rule of thumb is that the S/N ratio at the listener's ear should at a minimum be about 15 dB above the masked threshold for reliable signal detection. However, in noise levels above about 80 dBA, the signal levels required to maintain a S/N ratio of 15 dB above masked threshold may increase the hearing exposure risk, especially if signal presentation occurs frequently. Therefore, if lower S/N values become necessary, it is best to design contrasting signals which are unlike the masker in frequency and have modulated or alternating frequencies to grab attention.

4. Warning signals should not exceed the masked threshold by more than 30 dB to avoid verbal communications interference and operator annoyance (Sorkin, 1987).

5. As the SPL of the masker increases, the primary change in the masking effect is that it spreads upward in frequency, often causing signal frequencies which are higher than the masker to be missed (i.e., *upward masking*). Since most warning signal guidelines recommend that midrange and high-frequency signals (about 1000–4000 Hz) be used for detectability, it is important to consider that the masking effects of noise dominated by lower frequencies can spread upward and cause interference in this range. Therefore, if the noise has its most significant energy in this range, a low-frequency signal, say 500 Hz, may be necessary. However, as shown in Figure 3*a*, it must be kept in mind that the ear is not as sensitive to low frequencies, so the signal level must be set carefully to ensure reliable audibility.

6. Masking effects can also spread downward in frequency, causing signal frequencies below those of the masker to be raised in threshold (i.e., *remote masking*). The effect is most prominent at signal frequencies that are subharmonics of the masker. With typical industrial noise sources, remote masking is generally less of a problem than direct or upward masking.

7. When a signal must be localized, it is advantageous to include signal energy content below 1000 Hz and above 3000 Hz to maximize one's ability to locate the signal, taking advantage of both interaural time and interaural level differences, respectively.

8. In extremely loud environments of about 110 dB and above, nonauditory signal channels such as visual and vibrotactile should be considered as alternatives to auditory displays. They should also be used for redundancy in some lower level noises where the auditory signal may be overlooked or it blends in as the background noise varies and also where people who have hearing loss must attend to the signal.

9. Speech intelligibility in noise depends on a combination of complex factors and, as such, predictions based on simple S/N ratios should not be relied on. However, in very general terms, S/N ratios of 15 dB or higher should result in intelligibility performance above about 80% words correct for normal-hearing persons in broadband noise (Acton, 1970). Above speech levels of about 85 dBA, there is some decline in intelligibility even if the S/N ratio is held constant (Pollack, 1958). In very high noise levels, it is impractical and may pose additional hearing hazard risk to amplify the voice to maintain the high S/N ratios necessary for good intelligibility performance. The S/N ratio required for reliable intelligibility may be reduced via the use of certain techniques, such as reduction of speaker-to-listener distances, use of smaller vocabularies, provision of contextual cues in the message, use of the phonetic alphabet, and use of noise-attenuating headphones and noise-canceling microphones in electronic systems.

10. If hearing protection is necessary in a noisy environment, and if the detection, identification, discrimination, and/or localization of auditory signals is also necessary, and/or speech communications is needed, various types of augmented hearing protectors, as opposed to conventional passive devices, should be considered, albeit with great care as to their selection (Casali 2010a,b). Degradation of communications and situation awareness, while situation- and individual-specific, can create safety hazards for the individual who is occluded with an HPD.

11. Electronic speech communications systems should reproduce speech frequencies accurately in the range 500–5000 Hz, which encompasses the most sensitive range of hearing and includes

the speech sounds important for message under-standability. More specifically, because much of the information required for word discrimination lies in the consonants, which are in the higher end of the frequency range and of low power (while the power of the vowels is in the peaks of the speech waveform), the use of electronic peak clipping and reamplification of the waveform may improve intelligibility because the power of the consonants is thereby boosted relative to the vowels. Furthermore, to maintain intelligibility it is critical that frequencies in the region 1000–4000 Hz be faithfully reproduced in electronic communication systems. Filtering out of frequencies outside this range will not appreciably affect word intelligibility but will influence the quality of the speech.

12. Actual human speech typically results in higher intelligibility in noise than that of computer-generated speech, and there are also differences among synthesizers as to their intelligibility. Especially for critical message displays and annunciators, live, recorded, or digitized human speech may be preferable to synthesized speech (Morrison and Casali, 1994), and if synthesized speech is used, the selection of synthesizer must be made carefully.

# CHAPTER 24

# ILLUMINATION

**Peter R. Boyce**
**Consultant**
**Canterbury, United Kingdom**

## 1 INTRODUCTION

Illumination is the act of placing light on an object. By providing illumination, stimuli for the human visual system are produced and the sense of sight is allowed to function. With light we can see, without light we cannot see. This chapter is devoted to describing how to measure and produce illumination, the effects of different lighting conditions on visual performance and visual comfort, the photobiological and psychological effects of illumination, and the risks inherent in exposure to light.

## 2 MEASUREMENT OF ILLUMINATION

### 2.1 Photometric Quantities

Light is a part of the electromagnetic spectrum, lying between the wavelength limits 380–780 nm. What separates this wavelength region from the rest is that radiation in this region is absorbed by the photoreceptors of the human visual system, which initiates the process of seeing.

The most fundamental measure of the electromagnetic radiation emitted by a source is its radiant flux. This is a measure of the rate of flow of energy emitted and is measured in watts. The most fundamental quantity used to measure light is luminous flux. Luminous flux is radiant flux multiplied by the relative spectral sensitivity of the human visual system over the wavelength range 380–780 nm.

The relative spectral sensitivity of the human visual system is based on the perception of brightness associated with each wavelength. In fact, there are two different relative spectral sensitivities, sanctified by international agreement arranged through the Commission Internationale de l'Eclairage (CIE, 1983, 1990). There are two relative spectral sensitivities because the human visual system has two classes of photoreceptor: cones, which operate primarily when light is plentiful, and rods, which operate when light is very limited. These two photoreceptor types have different spectral sensitivities: the day photoreceptor, the cones, characterized by the CIE standard photopic observer, and the night photoreceptor, the rods, characterized by the CIE standard scotopic observer (Figure 1).

Luminous flux is used to quantify the total light output of a light source in all directions. While this is important, for lighting practice it is also important to be able to quantify the luminous flux emitted in a given direction. The measure that quantifies this concept is luminous intensity. Luminous intensity is the luminous flux emitted per unit solid angle in a specified direction.

**Figure 1** Relative luminous efficiency functions for (a) the CIE standard photopic observer and (b) the CIE standard scotopic observer. The CIE standard photopic observer is based on a 2-degree field of view. Also shown (c) is the relative luminous efficiency function for a 10-degree field of view in photopic conditions.

The unit of measurement is the candela, which is equivalent to one lumen per steradian. Luminous intensity is used to quantify the distribution of light from a luminaire.

Both luminous flux and luminous intensity have area measures associated with them. The luminous flux falling on unit area of a surface is called the illuminance. The unit of measurement of illuminance is the lumens per square meter, or lux. The luminous intensity emitted per unit projected area in a given direction is the luminance. The unit of measurement of luminance is the candela per square meter. The illuminance incident on a surface is the most widely used electric lighting design criterion. The luminance of a surface is a correlate of its brightness. Table 1 summarizes these photometric quantities and the relationship between illuminance and luminance.

Unfortunately for consistency, photometry has a long history that has generated a number of different units of measurement for illuminance and luminance. Table 2 lists some of the alternative units, together with the multiplying factors necessary to convert from the alternative unit to the System Internationale (SI) units of lumens per square meter for illuminance and candelas per square meter for luminance. The SI units will be used throughout this chapter.

Table 3 shows some illuminances and luminances typical of commonly occurring situations.

### 2.2 Colorimetric Quantities

The photometric quantities described above do not take into account the wavelength combination, that is, the color of the light being measured. There are two approaches to characterizing color, the color order system and the CIE colorimetry system.

#### 2.2.1 Color Order Systems

A color order system is a physical, three-dimensional representation of color space. It is three dimensional because colors have three separate subjective attributes; hue, brightness, and strength. Hue tells us whether the color is primarily red or yellow or green or blue. Brightness tells us to what extent the color transmits or reflects light. Strength tells us whether the color is strong or weak.

There are several different color order systems used in different parts of the world (Wyszecki and Stiles, 1982). Probably the most widely used is the Munsell Book of Color available from the Munsell Color Company. Figure 2 shows the three-dimensional color space of the Munsell system. The position of any color is identified by an alphanumeric code made up of three terms: hue, value, and chroma (e.g., a strong red is given the alphanumeric 7.5R/4/12). Hue, value, and chroma are related to the three attributes of color: hue, brightness, and strength, respectively. Building materials, such as paints, plastic, and ceramics, are commonly classified in terms of a color order system.

#### 2.2.2 CIE Colorimetric System

Sometimes, it is necessary to quantify the color of a light or a surface before either exists. To meet this

**Table 1 Photometric Quantities**

| Quantity | Definition | Units |
|---|---|---|
| Luminous flux | That quantity of radiant flux which expresses its capacity to produce visual sensation | lumen (lm) |
| Luminous intensity | The luminous flux emitted in a very narrow cone containing the given direction divided by the solid angle of the cone (i.e., luminous flux/unit solid angle) | candela (cd) |
| Illuminance | The luminous flux/unit area at a point on a surface | lumen meter$^{-2}$ (lm m$^{-2}$) |
| Luminance | The luminous flux emitted in a given direction divided by the product of the projected area of the source element perpendicular to the direction and the solid angle containing that direction, i.e. luminous flux/unit solid angle/unit area | candela meter$^{-2}$ (cd m$^{-2}$) |
| Reflectance | The ratio of the luminous flux reflected from a surface to the luminous flux incident on it: | |
| For a matte surface | $luminance = \dfrac{illuminance \times reflectance}{\pi}$ | |
| Luminance factor | The ratio of the luminance of a reflecting surface, viewed in a given direction to that of a perfect white uniform diffusing surface identically illuminated: | |
| For a nonmatte surface for a specific viewing direction and lighting geometry | $luminance = \dfrac{illuminance \times luminance\ factor}{\pi}$ | |

**Table 2 Common Photometric Units of Measurement for Illuminance and Luminance and Factors Necessary to Change Them to SI Units**

| Quantity | Unit | Dimensions | Multiplying Factor to Convert to SI Unit |
|---|---|---|---|
| Illuminance (SI unit = lumen meter$^{-2}$) | lux | lumen meter$^{-2}$ | 1.00 |
| | meter candle | lumen meter$^{-2}$ | 1.00 |
| | phot | lumen centimeter$^{-2}$ | 10,000.00 |
| | foot candle | lumen foot$^{-2}$ | 10.76 |
| Luminance (SI unit = candela meter$^{-2}$) | nit | candela meter$^{-2}$ | 1.00 |
| | stilb | candela centimeter$^{-2}$ | 10,000.00 |
| | — | candela inch$^{-2}$ | 1,550.00 |
| | — | candela foot$^{-2}$ | 10.76 |
| | apostilb[a] | lumen meter$^{-2}$ | 0.32 |
| | blondel[a] | lumen meter$^{-2}$ | 0.32 |
| | lambert[a] | lumen centimeter$^{-2}$ | 3,183.00 |
| | foot-lambert[a] | lumen foot$^{-2}$ | 3.43 |

[a]These four items are based on an alternative definition of luminance. This definition is that if the surface can be considered as perfectly matte, its luminance in any direction is the product of the illuminance on the surface and its reflectance. Thus, the luminance is described in lumens per unit area. This definition is deprecated in the SI system.

**Table 3 Typical Illuminance and Luminance Values**

| Situation | Illuminance on Horizontal Surface (lm/m$^2$) | Typical surface | Luminance (cd/m$^2$) |
|---|---|---|---|
| Clear sky in summer in northern temperate zones | 150,000 | Grass | 2,900 |
| Overcast sky in summer in northern temperate zones | 16,000 | Grass | 300 |
| Textile inspection | 1,500 | Light grey cloth | 140 |
| Office work | 500 | White paper | 120 |
| Heavy engineering | 300 | Steel | 20 |
| Residential road lighting | 10 | Asphalt road surface | 0.2 |
| Moonlight | 0.1 | Asphalt road surface | 0.002 |
**Figure 2** Organization of Munsell color order system. The hue letters are B = blue, PB = purple/blue, P = purple, RP = red/purple, R = red, YR = yellow/red, Y = yellow, GY = green/yellow, G = green, BG = blue/green.

need and to provide a more accurate characterization of color, the CIE has developed a system of colorimetry ranging from the simple to the complex (CIE, 1978, 1995, 2004a,b). The most fundamental characteristic of light is the spectral power distribution reaching the eye. It is this spectral power distribution that largely determines the color seen, although the perception of color is also influenced by the surroundings (Purves and Beau Lotto, 2003). Unfortunately, the implications of comparisons between spectral power distributions are difficult to comprehend. The CIE has developed two three-dimensional color spaces, both based on mathematical manipulations applied to spectral distributions (Robertson, 1977; CIE, 1978). These color spaces, Lab and Luv, provide a convenient means of quantifying color, the Lab space used mainly for object colors and the Luv space for self-luminous colors. If two colors have the same coordinates in one of these color spaces, under the same observing conditions they will appear the same. The distance between two colors in the color space is related to how easily they can be distinguished.

An earlier CIE color space, the 1964 Uniform Color Space, is used in the calculation of the CIE general color-rendering index, a single number index which is widely applied to light sources to indicate how accurately they render colors relative to some standard (CIE, 1995). Specifically, the positions in color space of 8 test colors, under a reference light source and under the light source of interest, are calculated. The separation between the two positions of each test color are calculated, the separations for all the test colors are summed and scaled to give a value of 100 when there is no separation for any of the test colors, i.e. for perfect color rendering.

It should be noted that the CIE general color-rendering index is a very crude metric. Different light sources have different reference light sources and the

summation means that light sources that render the test colors differently can have the same color-rendering index. Much more sophisticated are the color appearance models now available (Hunt, 1991; CIE, 2004b), but their existence has had little impact on lighting practice. Rather, a two-dimensional color surface is still widely used to characterize the color appearance of light sources and to define the acceptable color characteristics of light signals (CIE, 1994). This is the CIE 1931 chromaticity diagram shown in Figure 3. Essentially it is a slice through the color space at a fixed luminance. The curved boundary of the chromaticity diagram consists of the colors produced by single wavelengths. The equal-energy point in the center of the diagram corresponds to a colorless surface. The further the coordinates of a color are from the equal-energy point and the closer they are to the boundary, the greater the strength of the color. Figure 3 also shows several areas in which a signal light needs to fall if it is to be perceived as the specified color. The color appearance of nominally white light sources is conventionally described by their correlated color temperature. This is the temperature of the full radiator that is closest to the coordinates of the light source on the CIE 1931 chromaticity diagram (Wyszecki and Stiles 1982). A useful summary of these colorimetry systems is given in the tenth edition of the *Lighting Handbook* of the Illuminating Engineering Society of North America (IESNA, 2011).

## 2.3 Instrumentation

The instrumentation for measuring photometric and colorimetric quantities can be divided into laboratory and field equipment. Laboratory equipment tends to be large and/or sophisticated and hence expensive. Field equipment is small and portable. The luminous flux from a light source, the luminous intensity distribution
**Figure 3** CIE 1931 chromaticity diagram. The boundary curve is the spectrum locus with the wavelengths (nm) marked. The filled circle is the equal-energy point. The enclosed areas indicate the chromaticity coordinates of light signals that will be identified as the specified colors.

of a luminaire, and light source color properties are conventionally measured in the laboratory.

The two most widely used field instruments are the illuminance meter and the luminance meter. Illuminance meters have three important characteristics: sensitivity, color correction, and cosine correction. Sensitivity refers to the range of illuminances covered, the range desired being dependent on whether the instrument is to be used to measure daylight, interior lighting, or night-time exterior lighting. Color correction means that the illuminance meter has a spectral sensitivity matching the CIE standard photopic observer. Cosine correction means that the illuminance meter's response to light striking it from directions other than the normal follows a cosine law.

The luminance meter is designed to measure the average luminance over a specified area. The luminance meter has an optical system that focuses an image on a detector. Looking through the optical system allows the operator to identify the area being measured and usually displays the luminance of the area. The important characteristics of a luminance meter are its spectral response, its sensitivity, and the quality of its optical system. Again, a good luminance meter has a spectral response matching the CIE standard photopic observer. The sensitivity needed depends on the conditions under which it will be used. The quality of its optical system can be measured by its sensitivity to light from outside the measurement area (CIE, 1987).

Procedures for using illuminance or luminance meters in the field and for light measurements in the laboratory are described and referenced in the guidance published by national bodies [IESNA, 2011; Chartered Institution of Building Services Engineers (CIBSE), 2009; Society of Light and Lighting (SLL), 2009]. It should be noted that virtually all commercial instrumentation used to measure illuminance and luminance uses the CIE standard photopic observer as the basis of the instrument's spectral sensitivity, even when the instrument is designed to be used in mesopic and scotopic conditions.

Recently, another approach has been developed for rapidly acquiring the distribution of luminances over a large area. This approach uses multiple images captured by a digital camera and is called high-dynamic-range (HDR) imaging (Inanici, 2006). At the moment, HDR imaging is mainly being used for capturing luminance distributions that are subject to large and sudden changes, for example, sky luminances.

## 3 PRODUCTION OF ILLUMINATION

Illumination is produced naturally by the sun and artificially by electric light sources.

### 3.1 Daylight, Sunlight, and Skylight

Natural light is light received on Earth from the sun, either directly or after reflection from the moon. The prime characteristic of natural light is its variability. Natural light varies in magnitude, spectral content, and distribution with different meteorological conditions, at

different times of day and year, and at different latitudes. Moonlight is of little interest as a source of illumination, but daylight is used, and strongly desired, for the lighting of buildings. Daylight can be divided into two components, sunlight and skylight. Sunlight is light received at Earth's surface, directly from the sun. Sunlight produces strong, sharp-edged shadows. Skylight is light from the sun received at Earth's surface after scattering in the atmosphere. Skylight produces only weak, diffuse shadows. The balance between sunlight and skylight is determined by the nature of the atmosphere and the distance that the light passes through it. The greater is the amount of water vapor and the longer the distance, the higher is the proportion of skylight.

The illuminances on Earth's surface produced by daylight can cover a large range, from 150,000 lx on a sunny summer day to 1000 lx on a heavily overcast day in winter. Several models exist for predicting the daylight incident on a plane at different locations for different atmospheric conditions (Robbins, 1986). These models can be used to predict the contribution of daylight to the lighting of interiors. Alternatively, there are now available sets of measured illuminance or irradiance data for many different sites around the world. These make it possible to do climate-based modeling of daylight availability in interiors and the impact of daylight on the energy use of buildings (Mardaljevic et al., 2009).

The spectral composition of daylight also varies with the nature of the atmosphere and the path length through it. The correlated color temperature of daylight can vary from 4000 K for an overcast day to 40,000 K for a clear blue sky. For calculating the appearance of objects under natural light, the CIE recommends the use of one of three different spectral distributions corresponding to correlated color temperatures of 5503, 6504, and 7504 K (Wyszecki and Stiles, 1982).

## 3.2 Electric Light Sources

The lighting industry makes several thousand different types of electric lamps. Those used for providing illumination can be divided into three classes: incandescent, discharge, and solid state. Incandescent lamps produce light by heating a filament. Discharge lamps produce light by an electric discharge in a gas. Solid-state lamps produce light by the passage of an electric current through a semiconductor. Incandescent lamps can operate directly from mains electricity. Discharge lamps all require control gear between the lamp and the electricity supply, because different electrical conditions are required to initiate the discharge and to sustain it. Solid-state lamps require devices, called drivers, to limit the current through the semiconductor.

Electric light sources can be characterized on several different dimensions:

- *Luminous Efficacy*. The ratio of luminous flux produced to power supplied (lumens per watt). If the lamp needs control gear, the watts supplied should include the power demand of the control gear.
- *Correlated Color Temperature (CCT)*. A measure of the color appearance of the light produced, measured in degrees Kelvin (see Section 2.2.2).

- *CIE General Color-Rendering Index (CRI)*. A measure of the ability to render colors accurately (see Section 2.2.2).
- *Lamp Life*. The number of burning hours until either lamp failure or a stated percentage reduction in light output occurs. Lamp life can vary widely with switching cycle.
- *Run-Up Time*. The time from switch-on to full light output.
- *Restrike Time*. The time delay between the lamp being switched off before it will reignite.

Table 4 summarizes these characteristics for two incandescent lamp types, seven discharge lamp types, and one solid-state type that are widely used for illumination and gives the most common applications for each lamp type. The values in Table 4 should be treated as indicative only. Details about the characteristics of any specific lamp should always be obtained from the manufacturer.

## 3.3 Control of Light Distribution

Being able to produce light is only part of what is necessary to produce illumination. The other part is to control the distribution of light from the light source. For daylight, this is done by means of window shape, placement, and glass transmittance (Robbins, 1986). For electric light sources, it is done by placing the light source in a luminaire. The luminaire provides electrical and mechanical support for the light source and controls the light distribution. The light distribution is controlled by using reflection, refraction, or diffusion, individually or in combination (Simons and Bean, 2000). One factor in the choice of which method of light control to adopt in a luminaire is the balance desired between the reduction in the luminance of the light source and the precision required in light distribution. Highly specular reflectors can provide precise control of light distribution but do little to reduce source luminance. Conversely, diffusers make precise control of light distribution impossible but do reduce the luminance of the luminaire. Refractors are an intermediate case. The light distribution provided by a specific luminaire is quantified by the luminous intensity distribution. All reputable luminaire manufacturers provide luminous intensity distributions for their luminaires.

## 3.4 Control of Light Output

The control of daylight admitted through a window is achieved by mechanical structures, such as light shelves, or by adjustable blinds (Littlefair, 1990). Whenever the sun or a very bright sky is likely to be directly visible through a widow, some form of blind will be required. Blinds can take various forms, horizontal, Venetian, vertical, and roller being the most common. Blinds can also be manually operated or motorized, either under manual control or under photocell control. Probably the most important feature to consider when selecting a blind is the extent to which it preserves a view of the outside. Roller blinds that can be drawn down to a position where the sun and/or sky is hidden but the lower part of the widow is still open are an attractive option.

**Table 4  Properties of Some Electric Light Sources Widely Used for Illumination**

| Source | Luminous Efficacy (lm/W) | CCT (K) | CRI | Lamp Life (h) | Run-up Time (min) | Restrike Time (min) | Application |
|---|---|---|---|---|---|---|---|
| Incandescent | | | | | | | |
|   Tungsten | 8–14 | 2500–2700 | 100 | 1000 | Instant | Instant | Residential |
|   Tungsten–halogen | 15–25 | 2700–3200 | 100 | 1500–5000 | Instant | Instant | Residential, retail, display |
| Discharge | | | | | | | |
|   Fluorescent | 20–96 | 2700–17,000 | 50–98 | 8000–19,000 | 0.5 | Instant | Commercial |
|   Compact fluorescent | 20–70 | 2700–6500 | 80–90 | 5000–15,000 | 0.5–1.5 | Instant | Commercial, retail, residential |
|   Mercury vapor | 33–57 | 3200–3900 | 40–50 | 8000–10,000 | 4 | 3–10 | Older industrial and road |
|   Metal halide | 60–98 | 3000–6000 | 60–93 | 2000–10,000 | 1–8 | 5–20 | Industrial, commercial, retail and road |
|   Low-pressure sodium | 70–180 | N/A | N/A | 15,000–20,000 | 10–20 | 1 | Road |
|   High-pressure sodium | 53–142 | 1900–2150 | 19–65 | 10,000–20,000 | 3–7 | 0–1 | Industrial, road |
|   Induction | 47–80 | 2550–4000 | 80 | 60,000 | Instant | Instant | Road |
| Solid state | | | | | | | |
|   White light-emitting diode (LED) using phosphor | 21–33 | 3000–4000 | 70–83 | 40,000 | Instant | Instant | Residential, retail |

Roller blinds made of a mesh material can preserve a view through the whole window while reducing the luminance of the view out. Such blinds are an attractive option where the problem is an overbright sky but will be of limited value when a direct view of the sun is the problem. The same applies to low-transmission glass.

For electric light sources, control of light output is provided by switching or dimming systems. Switching systems can vary from the conventional manual switch to sophisticated daylight control systems that dim lamps near windows when there is sufficient daylight. Time switches are used to switch off all or parts of a lighting installation at the end of the working day. Occupancy sensors are used to switch off lighting when there is nobody in the space. Such switching systems can reduce electricity waste, but they will be irritating if they switch lighting off when it is required and they may shorten lamp life if switching occurs frequently. The factors to be considered when selecting a switching system are whether to rely on a manual or an automatic system and, if it is automatic, how to match the switching to the activities in the space. If your interest is primarily in reducing electricity consumption, a good principle is to use automatic switch-off and manual switch-on. This principle uses human inertia for the benefit of reducing energy consumption.

As for dimming systems, these all reduce light output and energy consumption, but a different system is required for each lamp type. The factors to consider when evaluating a dimming system are the range over which dimming can be achieved without flicker or the lamp extinguishing, the extent to which the color properties of the lamp change as the light output is reduced, and any effect dimming has on lamp life and energy consumption. There are large individual differences in preferred illuminances so whether or not giving people individual control of dimming will reduce energy consumption depends on the maximum illuminance provided (Boyce et al., 2006b).

## 4  FUNCTIONAL CHARACTERISTICS OF HUMAN VISUAL SYSTEM

### 4.1  Visual System Structure

Illumination is important to humans because it alters the stimuli to the visual system and the operating state of the visual system itself. Therefore, an understanding of the capabilities of the visual system and how they vary with illumination is important to an understanding of the effects of illumination. The visual system is composed of the eye and brain working together. Light entering the eye is brought to focus on the retina by the combined optical power of the air/cornea surface and the lens of the eye. The retina is really an extension of the brain, consisting of two different types of photoreceptors and numerous nerve interconnections. At the photoreceptors, the incident photons of light are absorbed and converted to electrical signals. The nerve interconnections take these signals and carry out some basic image processing. The processed image is transmitted up the optic nerve of each eye to the optic chiasma, where nerve fibers from the two eyes are combined and transmitted to the left
**Figure 4**   Section through the eye adjusted for near and distant vision and a schematic diagram of the binocular nerve pathways of the visual system.

and right parts of the visual cortex. It is in the visual cortex that the signals from the eye are interpreted in terms of past experience (Figure 4).

Many of the capabilities of the visual system can be understood from the organization of the retina. The two types of visual photoreceptors, called rods and cones from their anatomical appearance, have different wavelength sensitivities and different absolute sensitivities to light and are distributed differently across the retina.

Rods are the more sensitive of the two and effectively provide a night retina. Cones are less sensitive to light and operate during daytime. In fact, there are three types of cones, each with a different spectral sensitivity. These cones are commonly called long-, middle-, and short-wavelength cones, from their regions of maximum spectral sensitivity. These three cone types combine together to give the perception of color. Figure 5 shows the distribution of rods and cones across the retina. Cones are concentrated in a small central area of the

retina called the fovea that lies where the visual axis of the eye meets the retina, although there are cones distributed evenly across the rest of the retina. Rods are absent from the fovea, reaching their maximum concentration about $20°$ from the fovea. This variation in concentration of rods and cones with deviation from the fovea is amplified by the number of photoreceptors connected to each optic nerve fiber. In the fovea, the ratio of photoreceptors to optic nerve fibers is close to 1 but increases rapidly as the deviation from the fovea increases. The net effect of this structure is to provide different functions for the fovea and the periphery. The fovea is the part of the retina which provides fine discrimination of detail. The rest of the retina is primarily devoted to detecting changes in the visual environment that require the attention of the fovea.

## 4.2  Wavelength Sensitivity

The rod and cone photoreceptors have different absolute spectral sensitivities (Figure 6). The spectral response of
**Figure 5** Density of rod and cone photoreceptors across the retina on a horizontal meridian. (After Osterburg, G., *Acta Ophthalmologica*, Vol. 13, Suppl. 6, 1935.)

**Figure 6** Log relative spectral sensitivity of rod and cone photoreceptors plotted against wavelength. (After Wald, G., *Science,* Vol. 101, p. 653, 1945.)

the cones lies between 380 and 780 nm with the peak sensitivity occurring at 555 nm. The spectral response of the rods lies between 380 and 780 nm with the peak at 507 nm. The peak sensitivity of the rods is much greater than that of the cones. These spectral sensitivities form the basis of the CIE standard observers and hence the photometric quantities discussed in Section 2.1. By adjusting the spectral emission of a light source to lie within the most sensitive part of the spectral response of the visual system, lamp manufacturers are able to vary the number of lumens emitted for each watt of power applied.

## 4.3 Adaptation

The visual system can operate over a range of about 12 log units of luminance, from a luminance of $10^{-6}$ to $10^6$ cd/m$^2$, from starlight to bright sunlight. But it cannot cover this range simultaneously. At any instant in time, the visual system can cover a range of 2 or 3 log units of luminance. Luminances above this limited range are seen as glaringly bright, those below as undifferentiated black. The capabilities of the visual system depend on where in the complete range of luminances it is adapted. Three different functional ranges of luminance are conventionally identified: the photopic, mesopic, and scotopic. Table 5 summarizes the visual system capabilities in each of these functional ranges.

The visual system continuously adjusts its state of adaptation through three mechanisms: neural, mechanical, and photochemical. These three mechanisms differ in their speed and range of adjustment. The neural mechanism, which is based in the retina, operates in milliseconds and covers a range of two to three log units in luminance. The mechanical mechanism involves the expansion and contraction of the iris. The consequent changes in pupil size take about a second but cover less than one log unit in luminance. The photochemical mechanism covers the whole range of luminance but is slow, the changes taking minutes. The exact time will depend on the starting and finishing luminances. If both starting and finishing luminances for the adaptation are greater than 3 cd/m$^2$, only cones are involved. As the time constant for cones is of the order of 2–3 min, adaptation takes only a few minutes. When the starting luminance is in the operating range of the cones and the finishing luminance is within the operating range of the rods, a two-stage adaptation process occurs involving both cones and rods. As rods have a time constant around 7–8 min, the adaptation time is much longer. Complete adaptation from a high photopic luminance to darkness can take up to an hour.

**Table 5 Functional Ranges of Visual System Capabilities**

| Operating State Range | Luminance (cd/m$^2$) | Active Photoreceptors | Peak Wavelength Sensitivity | Characteristics |
|---|---|---|---|---|
| Photopic | > 3 | Cones | 555 nm | Good color vision Good resolution |
| Scotopic | < 0.001 | Rods | 507 nm | No color vision Poor resolution Fovea ''blind'' |
| Mesopic | > 0.001 and <3 | Cones and rods | 555 nm in fovea, between 555 nm and 507 nm elsewhere | Reduced color vision, reduced resolution relative to photopic |

Interior lighting is almost always sufficient for the visual system to be operating in the photopic region. Exterior lighting on roads and in urban areas is usually sufficient to keep the visual system operating in the low-photopic or high-mesopic regions. It is in very rural areas, at sea, or underground, where there is neither exterior lighting nor moonlight, that the visual system reaches the scotopic state. The speed of adaptation is important where a large and sudden change in the luminance occurs. Examples of situations where this happens are the entrance to road tunnels during daytime (Bourdy et al., 1987) and the onset of emergency lighting during a power failure (Boyce, 1985). These problems are overcome either by installing a gradual reduction in luminance, which allows more time for adaptation to occur, or by setting a minimum luminance within the neural adaptation range.

### 4.4   Color Vision

When photopically adapted, the visual system can discriminate many thousands of colors. This ability to discriminate colors reduces as the adaptation luminance decreases through the mesopic region and vanishes in the scotopic vision. This is because color vision is mediated by the cone photoreceptors. Different light sources have different spectral emissions and hence render colors differently. To ensure good color discrimination, it is necessary to use a light source that has a high CIE general color-rendering index and that produces sufficient light to ensure the visual system is operating in the photopic state.

### 4.5   Receptive Field Size and Eccentricity

The retina is organized in such a way that increasing numbers of photoreceptors are connected to each optic nerve fiber as the deviation from the fovea increases.

   This feature of the visual system is important when detection of a stimulus is necessary and it can occur anywhere in the visual field. The visual system will normally operate by first detecting the stimulus off-axis, that is, in the peripheral visual field, and then turning the eye so that the stimulus is brought onto the fovea for detailed examination. In order to identify a stimulus off-axis, the stimulus should be clearly different from its background, in luminance or color, and should change in space or time, that is, it should either move or flicker. A flickering light is commonly used to draw drivers' attention to important signs placed beside or above the road.

### 4.6   Meaningful Stimulus Parameters

Any stimulus to the visual system can be described by five parameters: its visual size, luminance contrast, chromatic contrast, retinal image quality, and retinal illumination. These parameters are important in determining the extent to which the visual system can detect and identify the stimulus.

### 4.6.1   Visual Size

The visual size of a stimulus describes how big the stimulus is. The larger a stimulus is, the easier it is to detect.

There are several different ways to express the size of a stimulus presented to the visual system, but all of them are angular measures. The visual size of a stimulus for detection is best given by the solid angle the stimulus subtends at the eye. The solid angle is given by the quotient of the areal extent of the object and the square of the distance from which it is viewed. The larger the solid angle is, the easier the stimulus is to detect.

   The visual size for resolution is usually given as the angle the critical dimension of the stimulus subtends at the eye. What the critical dimension is depends on the stimulus. For two points, the critical dimension is the distance between the two points. For two lines, it is the separation between the two lines. For a Landolt ring, it is the gap width. The larger is the visual size of detail in a stimulus, the easier it is to resolve the detail.

   For complex stimuli, the measure used to express their dimensions is the spatial frequency distribution. Spatial frequency is the reciprocal of the angular subtense of a critical detail, in cycles per degree. Complex stimuli have many spatial frequencies and hence a spatial frequency distribution. The match between the spatial frequency distribution of the stimulus and the contrast sensitivity function of the visual system (see Section 5.2) determines if the stimulus will be seen and what detail will be resolved.

   Lighting can change the visual size of three-dimensional stimuli by casting shadows that extend or diminish the apparent visual size of the stimulus.

### 4.6.2   Luminance Contrast

The luminance contrast of a stimulus quantifies its luminance relative to its background. The higher the luminance contrast is, the easier it is to detect the stimulus. There are two different forms of luminance contrast. For stimuli that are seen against a uniform background, luminance contrast is defined as

$$C = |L_t - L_b|/L_b$$

where

$\quad C$ = luminance contrast
$\quad L_b$ = Luminance of the background
$\quad L_t$ = Luminance of the detail

   This formula gives luminance contrasts that range from 0 to 1 for stimuli that have details darker than the background and from 0 to infinity for stimuli that have details brighter than the background. It is widely used for the former, for example, printed text.

   For stimuli which have a periodic pattern, for example, a grating, the luminance contrast or modulation is given by

$$C = (L_{max} - L_{min})/(L_{max} + L_{min})$$

where

$\quad C$ = Luminance contrast
$\quad L_{max}$ = maximum luminance
$\quad L_{min}$ = minimum luminance

   This formula gives luminance contrast that ranges from 0 to 1.

Lighting can change the luminance contrast of a stimulus by producing disability glare in the eye or veiling reflections from the stimulus or by changing the incident spectral radiation when colored stimuli are involved.

### 4.6.3  Chromatic Contrast

Luminance contrast uses the total amount of light emitted from a stimulus and ignores the wavelengths of the emitted light. It is the wavelengths emitted from the stimulus that largely determine its color. It is possible to have a stimulus with zero luminance contrast that can still be detected because it differs from its background in color, that is, it has chromatic contrast. There is no widely accepted measure of chromatic contrast, although various suggestions have been made (Tansley and Boynton, 1978). Fortunately, chromatic contrast only becomes important for detection when luminance contrast has reached a low level, typically less than 0.2 (O'Donell and Colombo, 2008).

Lighting can alter chromatic contrast by using light sources with different spectral emission characteristics.

### 4.6.4  Retinal Image Quality

As with all image-processing systems, the visual system works best when it is presented with a clear, sharp image. The sharpness of the stimulus can be quantified by the spatial frequency distribution of the stimulus; a sharp image will have high spatial frequency components present, a blurred image will not.

The sharpness of the retinal image is determined by the stimulus itself, the extent to which medium through which it is transmitted scatters light, and the ability of the visual system to focus the image on the retina. Lighting can do little to alter any of these factors, although it has been shown that light sources that are rich in the short wavelengths produce smaller pupil sizes and these tend to improve visual acuity slightly (Berman et al., 2006). The suggested explanation is that the smaller pupil sizes produce greater depth of field and hence better retinal image quality (Berman et al., 1993).

### 4.6.5  Retinal Illumination

The retinal illumination determines the state of adaptation of the visual system and therefore alters its capabilities. The retinal illumination is determined by the luminance in the visual field modified by the pupil size. Retinal illumination is measured in trolands, a quantity formed from the product of the luminance of the visual field and the pupil size (Wyszecki and Stiles, 1982). Illuminances and surface reflectances determine the luminances of the visual field. Luminances and light spectrum determine pupil size.

## 5   EFFECTS ON THRESHOLD VISUAL PERFORMANCE

Qualitatively, threshold visual performance is the performance of a visual task close to the limits of what is possible. Quantitatively, it is the performance of a task at a level such that it can be correctly carried out on 50% of the occasions it is undertaken. Threshold visual performance is affected by many different variables. For example, visual acuity is affected by the form of the target used, the luminance contrast of the target, the duration for which it is presented, where in the visual field it appears, and the luminance of the surround relative to the luminance of the immediate background. In this discussion of threshold visual performance, attention will be limited to the effects of variables that are controlled by the lighting system, that is, the adaptation luminance and the spectral content of the light. Information on the influence of other variables can be obtained from Boff and Lincoln (1988). In the data presented it will be assumed that the observer is fully adapted to the prevailing luminance, the image of the target is on the fovea, the target is presented for an unlimited time, and that observer is correctly refracted.

### 5.1   Visual Acuity

Visual acuity is the limit in the ability to resolve detail. Visual acuity has been frequently measured using gratings or Landolt C's. Visual acuity can be quantified as the angle subtended at the eye by the size of detail that can be correctly detected on 50% of the occasions it is presented.

No matter what target is used visual acuity improves, that is, the size of detail that can be resolved decreases as adaptation luminance increases. Figure 7 shows that as adaptation luminance increases from scotopic to photopic conditions, visual acuity increases, asymptotically approaching a maximum at high luminances. Table 3 gives some luminances typically found in interior and exterior lighting installations. Given a value for the adaptation luminance, Figure 7 can be used to determine if detail of a given size can be resolved or not. A useful rule of thumb is that the detail needs to be four times bigger than the visual acuity limit if it is to be resolved sufficiently quickly to avoid affecting visual performance (Bailey et al., 1993) .

As for light spectrum, for a lamp producing white light, then, at the same luminance, a spectrum that produces a smaller pupil size will enhance visual acuity slightly (Berman et al., 2006).

**Figure 7**   Effect of adaptation luminance on gap size of Landolt C target which can just be resolved. (After Shlaer, S., *Journal of General Physiology*, Vol. 21, p. 165, 1937.)
**Figure 8** Effect of adaptation luminance on contrast sensitivity function. Contrast sensitivity plotted against spatial frequency (cycles/degree) for different adaptation luminances. (After Savoy, R. L., and MaCann, J. J., *Journal of the Optical Society of America*, Vol. 65, p. 343, 1975.)

## 5.2 Contrast Sensitivity Function

Contrast sensitivity is the reciprocal of the luminance contrast that can be detected on 50% of the occasions it is presented. Contrast sensitivity is usually measured using a sinusoidal grating target. The contrast sensitivity function is contrast sensitivity plotted against the spatial frequency of the sinusoidal target.

Figure 8 shows the effect of adaptation luminance on the contrast sensitivity function. It shows that as the adaptation luminance increases from scotopic to photopic conditions, the contrast sensitivity increases for all spatial frequencies; the spatial frequency at which the peak contrast sensitivity occurs increases and the highest spatial frequency that can be detected also increases. Figure 8 can be used to determine if a given target will be visible by breaking the target into its spatial frequency components and determining if any of the components are within the limit set by the contrast sensitivity function (Sekular and Blake, 1994). The target will only be visible if at least one of its components falls within this limit, although it should be noted that the appearance of the target will be different depending on which component or components are visible. As a rule of thumb, for a target to be easily seen, it is necessary for the luminance contrast to be at least twice the contrast threshold.

As for the light spectrum, the results of Berman et al. (2006) imply that the contrast sensitivity function is somewhat influenced by different white-light spectra.

## 5.3 Temporal Sensitivity Function

The temporal sensitivity function shows percentage modulation amplitude plotted against the frequency of the modulation. Figure 9 shows the effect of adaptation luminance on the temporal sensitivity function. It shows

**Figure 9** Effect of adaptation luminance on temporal sensitivity function. Percentage modulation amplitude plotted against frequency (Hz) for different levels of retinal illumination. The retinal illuminations are: filled square = 0.06 trolands; open square = 0.65 trolands; open, inverted triangle = 7.1 trolands; open, upright triangle = 77 trolands; open circle = 850 trolands; filled circle = 9300 trolands. (After Kelly, D. H., *Journal of the Optical Society of America*, Vol. 51, p. 422, 1961.)

that as the adaptation luminance increases from mesopic to photopic conditions, the temporal sensitivity increases for all frequencies; the frequency at which the peak temporal sensitivity occurs increases, and the highest frequency that can be detected also increases. Figure 9 can be used to determine if a given temporal variation will be visible by breaking the waveform representing

the light fluctuation into its frequency components and determining if any of the components are within the limit set by the temporal sensitivity function. The fluctuation will only be visible if at least one of its frequency components falls within this limit.

Temporal fluctuation in luminous flux (i.e., flicker) is undesirable in lighting installations. To eliminate flicker, it is necessary to increase the frequency and/or decrease the modulation sufficiently to take their combination outside the limits set by the temporal sensitivity function. In practice, this is easily done. Incandescent lamps have sufficient thermal inertia to ensure that, even though the frequency of the fluctuation is only twice the supply frequency (120 Hz for a 60-Hz electrical supply), the modulation is small so there is little chance of seeing flicker from such a lamp. Discharge and solid-state lamps do not have thermal inertia so their modulation can be high where there is no phosphor used to modify the spectrum of the light emitted. Where a phosphor

is used, the persistence of the phosphor will tend to reduce the modulation. To ensure that discharge and solid-state lamps do not produce visible flicker, it is best to use a control gear that operates at a high frequency or, alternatively, in the case of solid-state lamps, zero frequency, that is, from a direct-current supply.

## 5.4 Color Discrimination

The ability to discriminate between two colors of the same luminance depends on the difference in spectral power distribution of the light received at the eye. Figure 10 shows the MacAdam ellipses, the area around a number of chromaticities, each magnified 10 times, within which no discrimination of color can be made, even under side-by-side comparison conditions (Wyszecki and Stiles, 1982).

The effect of illuminance on the ability to discriminate between colors is limited in the photopic region,

**Figure 10** MacAdam ellipses plotted on the CIE 1931 chromaticity diagram. The boundary of each ellipse represents 10 times the standard deviation of color matches made for the indicated chromaticity. (After MacAdam, D. L., *Journal of the Optical Society of America*, Vol. 32, p. 247, 1942.)

an illuminance of 300 lx being sufficient for good color judgment work (Cornu and Harlay, 1969). As the visual system enters the mesopic region, the ability to discriminate colors deteriorates and ultimately fails as the scotopic region is reached.

The effect of the light spectrum is much more important. The position of a color on the CIE 1931 chromaticity diagram is determined by the spectrum of the light and, if it is reflected from or transmitted through a surface, the spectral reflectance or transmittance of that surface. Therefore, by changing the light spectrum emitted by the lamp, it is possible to make colors easily discriminable or difficult to discriminate. The careful choice of light source is important wherever good color discrimination is important.

## 5.5 Interactions

The fact that there are many other variables besides adaptation luminance and light spectrum that influence threshold visual performance has been mentioned earlier. It is now necessary to introduce another complication, namely, interaction between the various components of visual system performance. As an example, consider the effect of luminance contrast on visual acuity. Visual acuity is conventionally measured using targets with a high luminance contrast. However, as the luminance contrast of the target is decreased, visual acuity also worsens. Similarly, the temporal sensitivity function as presented applies to a uniform luminance field. If the field has a pattern and hence a distribution of spatial frequencies, the temporal sensitivity function may be changed (Koenderink and Van Doorn, 1979).

Put crudely, what this means is that as visual performance gets closer to threshold, almost everything about the stimulus presented to the visual system becomes important. Further details on some of the interactions that occur are given in Boff and Lincoln (1988)

## 5.6 Approaches to Improving Threshold Visual Performance

Working close to threshold is not easy. In fact, it can be argued that the main function of anyone designing illumination is to provide conditions that avoid the need to use the visual system close to threshold. However, if this is required, then the following steps can be taken to improve threshold visual performance. Not all of the following steps will be possible in every situation and not all are appropriate for every problem. The discussion above should indicate which approach is likely to be most effective.

### Changing the Task:

- Increase the size of the detail in the task.
- Increase the luminance contrast of the detail in the task.
- Present the task so that it can be looked at directly, that is, with the fovea.
- Change the color of the target to make it more conspicuous
- Reduce the velocity of the task.
- Present the task for a longer time.

### Changing the Environment:

- Increase the adaptation luminance.
- Select a lamp with better color properties.
- Design the lighting so that it is free from disability glare and veiling reflections (see Section 7).

## 6 EFFECTS ON SUPRATHRESHOLD VISUAL PERFORMANCE

Suprathreshold visual performance is the performance of tasks that are easily visible because the stimuli they present to the visual system are well above those associated with threshold conditions. This raises the question as to why lighting conditions make a difference to task performance once what has to be seen is clearly visible. The answer is that although the stimuli are clearly visible, lighting influences the speed with which the visual information extracted from the stimuli can be processed. The aspect of lighting which determines this effect is the retinal illumination. The retinal illumination is determined by the luminance of the visual field that is viewed and hence by the illuminance on the surfaces which form that field.

### 6.1 Relative Visual Performance Model for On-Axis Detection

The relative visual performance (RVP) model of visual performance is an empirical model of the reaction time for the detection of different visual stimuli seen on the fovea for a range of adaptation luminances, luminance contrasts, and visual sizes (Rea and Ouellette, 1988, 1991). Figure 11 shows the form of the RVP model for four different visual size tasks, each surface being for a range of contrasts and retinal illuminances. The overall shape of the relative visual performance surface has been described as a plateau and an escarpment (Boyce and Rea, 1987). In essence what it shows is that the visual system is capable of a high level of visual performance over a wide range of visual sizes, luminance contrasts, and retinal illuminations (the plateau), but at some point either visual size or luminance contrast or retinal illumination will become insufficient and visual performance will rapidly collapse (the escarpment) toward threshold. The existence of a plateau of visual performance, or rather a near plateau because there is really a slight improvement in visual performance across the plateau, implies that for a wide range of visual conditions visual performance changes very little with changes in the lighting conditions.

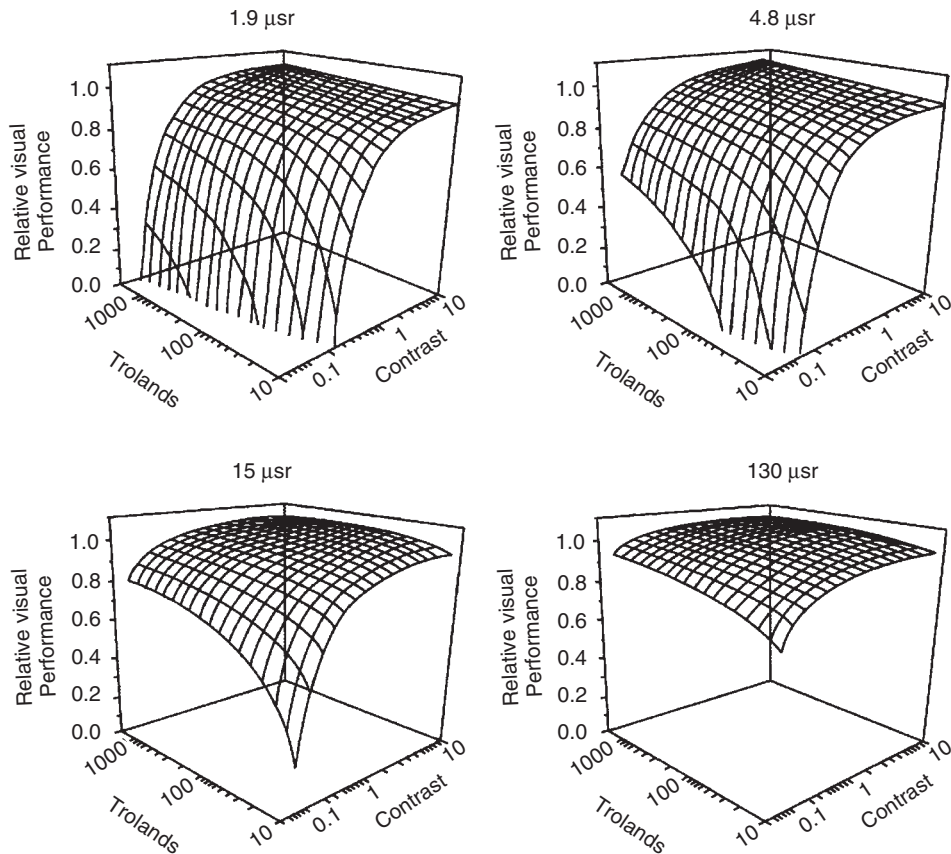
The RVP model of suprathreshold visual performance provides a quantitative means of predicting the effects of changing either task size or contrast or the adaptation luminance on visual performance. It has been developed using rigorous methodology and has been validated against independently collected data (Eklund et al., 2001; Boyce, 2003). However, it is important to note that it should only be applied to a limited range of tasks. Specifically, it is most appropriate for tasks where task performance is dominated by the visual component (see Section 6.3), which do not require the use of off-axis vision to any extent; present stimuli to the visual system that can be completely characterized by


**Figure 11** Relative visual performance surfaces plotted against retinal illumination, in trolands, and luminance contrast for four stimuli subtending four different solid angles, measured in microsteradians. (After Rea, M. S., and Ouellette, M. J., *Lighting Research and Technology*, Vol. 23, p. 135, 1991.)

visual size, luminance contrast, and background luminance; and have values for these variables that fall within the ranges used to develop the model. Where the task involves chromatic contrast as well as luminance contrast, the RVP model is likely to be misleading and the light spectrum used for illumination will be important. Where the task is achromatic, the light spectrum is not likely to be important for suprathreshold visual performance unless performance is limited by the size of detail that needs to be seen (Boyce et al., 2003).

## 6.2 Visual Search

One class of tasks for which the RVP model is not applicable is comprised of those in which the object to be detected can appear anywhere in the visual field. These tasks involve visual search. Visual search is typically undertaken through a series of eye fixations, the fixation pattern being guided either by expectations about where the object to be seen is most likely to appear or by what part of the visual scene is most important. Typically, the object to be detected is first detected off-axis and then confirmed or resolved by an on-axis

fixation. The speed with which a visual search task is completed depends on the visibility of the object to be found, the presence of other objects in the search area, and the extent to which the object to be found is different from the other objects. The simplest visual search task is one in which the object to be found appears somewhere in an otherwise empty field, for example, paint defects on a car body. The most difficult visual search task is one where the object to be found is situated in a cluttered field and the clutter is very similar to the object to be found, for example, searching for a face in a crowd.

The lighting conditions necessary to achieve fast visual search are similar to those used to improve foveal threshold visual performance. By improving foveal threshold visual performance, the peripheral threshold visual performance is also improved so the object to be found is made more visible. The lighting required for fast visual search will have to be matched to the physical characteristics of the object to be found. For example, if the object is two dimensional and of matte reflectance located on a matte background, increasing the adaptation luminance is about the only option. However, if the object is three dimensional and has a specular reflectance

component, then light distribution can be used to increase the apparent size by casting shadows and the luminance contrast of the object by producing highlights on or around the object—changes which will be much more effective than simply increasing the adaptation luminance. Likewise, if the object is distinguished from its background primarily by color, the light spectrum used is an important consideration. It is this need to match the lighting conditions to the nature of the objects to be found which makes the design of lighting installations for visual inspection tasks so difficult and diverse (IESNA, 2011; Boyce, 2003).

The extent to which a lighting installation is effective in revealing an object can be estimated from the object's visibility lobe (Inditsky et al., 1982). The visibility lobe is the distribution of the probability of detecting the object within one eye fixation pause. This probability is a maximum when the object is viewed on-axis and decreases with increasing deviation from the fovea. The probability distribution is assumed to be radially symmetrical about the visual axis, resulting in circles around the fixation point, each circle having a given probability of detection within one fixation pause. For objects which appear on a uniform field, the visibility lobe is based on the detection of the object. For objects which appear among other similar objects, the visibility lobe is based on the discriminability of the object from the others surrounding it. Visual search will be fastest for objects which have the largest visibility lobe.

## 6.3 Visual Performance, Task Performance, and Productivity

Figure 12 shows the relationships between the stimuli to the visual system and their impact on visual performance, task performance, and productivity. The stimuli to the visual system, including the retinal illumination, determine the operation of the visual system and hence the level of visual performance achieved. This visual performance then contributes to task performance. It is important to point out that visual performance and task performance are not necessarily the same. Task performance is the performance of the complete task. Visual performance is the performance of the visual component of the task. Task performance is what is needed in order to measure productivity and to establish cost–benefit ratios. Visual performance is the only thing that changing the lighting conditions can affect directly.

Most apparently visual tasks have three components: visual, cognitive, and motor. The visual component refers to the process of extracting information relevant

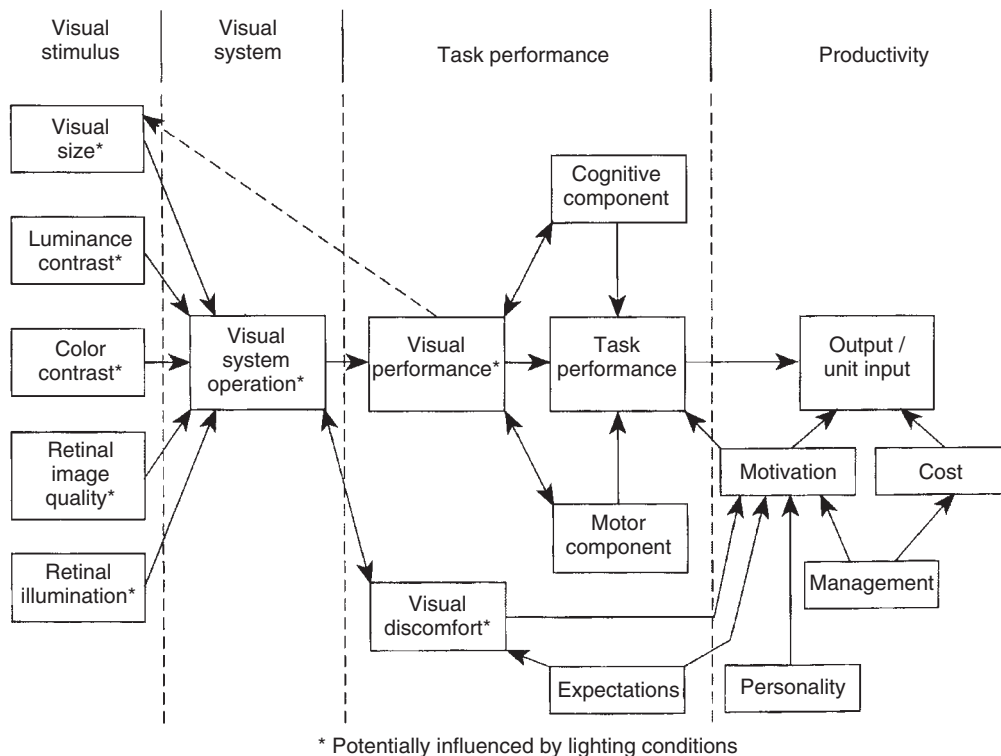

**Figure 12** Schematic of relationships between stimuli to the visual system and their impact on visual performance, task performance, and productivity. The arrows indicate the direction of the effects. The dotted arrow between visual performance and visual size indicates that, if visual performance is poor, a common response is to move closer to the stimulus to increase its visual size.

to the performance of the task using the sense of sight. The cognitive component is the process by which sensory stimuli are interpreted and the appropriate action determined. The motor component is the process by which the stimuli are manipulated to extract information and/or the actions decided upon are carried out. Every task is unique in its balance between visual, cognitive, and motor components and hence in the effect lighting conditions have on task performance. It is this uniqueness which makes it impossible to generalize from the effect of lighting on the performance of one task to the effect of lighting on the performance of another. The RVP model for on-axis tasks and the visual search models discussed above can be used to quantify the effects of lighting conditions on visual performance, but there is no general model to translate those results to task performance.

### 6.4  Approaches to Improving Suprathreshold Visual Performance

The main purpose of lighting installations is to ensure that people can perform the work they need to do quickly, easily, comfortably, and safely. To achieve this desirable aim, it is necessary to provide lighting which ensures people are working on the plateau of visual performance and not on the escarpment. The RVP model of visual performance provides a simple means of checking whether lighting is adequate for the visual performance of many on-axis tasks. The visibility lobe provides an approach to quantifying the effect of lighting conditions on visual search tasks. Alternatively, most countries have well-established recommendations for the illuminances to be provided for working interiors (IESNA, 2011; CIBSE, 2009). Most of these recommendations easily exceed what would be deduced as necessary from a consideration of visual performance alone.

Although the discussion above has focused on lighting conditions, it is important to recognize that improving suprathreshold visual performance can be achieved by changing the characteristics of the task as well as the lighting. The following list is divided into two parts: task changes and lighting changes. Not all of the following suggestions will be possible in every situation and not all are appropriate for every problem.

#### Changing the Task:

- Increase the size of the detail in the task.
- Increase the luminance contrast of the detail in the task.
- For off-axis tasks in a cluttered field, make the object to be detected clearly differ from the surrounding objects on as many different dimensions as possible, for example, size, contrast, color, and shape.
- Ensure the object presents a clear, sharp image on the retina.

#### Changing the Environment:
- Increase the adaptation luminance.
- Where the task involves color, select a lamp with better color properties.

- Design the lighting so that it is free from disability glare and veiling reflections (see Section 7).
- Design the lighting to increase the apparent size or luminance contrast of the object.

## 7  EFFECTS ON COMFORT

Lighting installations are rarely designed for visual performance alone. Visual comfort is almost always a consideration. The aspects of lighting which cause visual discomfort include those relevant to visual performance and extend beyond them. This is because the factors relevant to visual performance are generally restricted to the task and its immediate area, whereas the factors affecting visual discomfort can occur anywhere within the lit space.

### 7.1  Symptoms and Causes of Visual Discomfort

Visual discomfort can give rise to an extensive list of symptoms. Among the more common are red, sore, itchy, and watering eyes; headaches and migraine attacks; and aches and pains associated with poor posture. Visual discomfort is not the only possible source of these symptoms. All can have other causes. It is this vagueness which makes it essential to consider the nature of the visual environment before ascribing any of these symptoms to the lighting conditions.

Features of the visual environment that can cause visual discomfort are as follows:

*Visual Task Difficulty*. The visual system is designed to extract information from the visual environment. Any visual task that is close to threshold contains information that is difficult to extract. The usual reaction to a high level of visual difficulty is to bring the task closer to increase its visual size. As the task is brought closer, the accommodation mechanism of the eye has to adjust to keep the retinal image sharp. This adjustment can lead to muscle fatigue and hence symptoms of visual discomfort.

*Under- and Overstimulation*. The visual system is designed to extract information from the visual environment. Discomfort occurs either when there is no information to be extracted or when there is an excessive amount of repetitive information. Examples of no information occur when driving in fog or in a "whiteout" snowstorm. In both cases, the visual system is searching for information which is hidden but which may appear suddenly and require a rapid response. The stress experienced while driving in these conditions is a common experience. As for overstimulation, the important point is not the total amount of visual information, but rather the presence of large areas of the same spatial frequency. Wilkins (1993) has associated the presence of large areas of specific spatial frequencies in printed text with the occurrence of headaches, migraines, and reading difficulties.

*Distraction*. The visual system is designed to extract information from the visual environment. To do this, it has a large peripheral field which detects the presence of objects which are then examined using the small, high-resolution fovea. For this system to work, objects in the peripheral field that are bright, moving, or flickering have to be easily detected. If, upon examination, these bright, moving, or flickering objects prove to be of little interest, they become sources of distraction because their attention-gathering power is not diminished after one examination. Ignoring objects that automatically attract attention is stressful and can lead to symptoms of visual discomfort.

*Perceptual Confusion*. The visual system is designed to extract information from the visual environment. The visual environment consists of a pattern of luminances developed from the differences in reflectance of the surfaces in the field of view and the distribution of illuminance on those surfaces. Perceptual confusion occurs when there is a pattern of luminances present which is solely related to the illuminance distribution and conflicts with the pattern of luminance associated with the reflectances of the surfaces.

## 7.2 Lighting Conditions That Can Cause Discomfort

There are many different aspects of lighting that can cause discomfort. Insufficient light for the performance of a task has been discussed earlier and will not be discussed again. Rather, attention will be devoted to flicker, glare, shadows, and veiling reflections. It should be noted that whether or not these aspects of lighting cause discomfort will depend on the context. All can be used to positive effect in some contexts.

**Flicker**  A lighting installation that produces visible flicker will be almost universally disliked unless it is being used for entertainment. Large individual differences in the sensitivity to flicker imply that a clear safety margin is necessary. This can be achieved by high-frequency operation and/or the mixing of light from lamps powered from different phases of the electricity supply. The same approaches, which will result in a changed frequency and/or a reduced percentage modulation, can be used to diminish any stroboscopic illusions. The use of high-frequency control gear has been associated with a reduction in the prevalence of headaches under fluorescent lighting (Wilkins et al. 1989).

**Glare**  Glare occurs in two ways. First, it is possible to have too much light. Too much light produces a simple photophobic response in which the observer screws up his eyes, blinks, or looks away. Too much light is rare indoors but is common in full sunlight. Second, glare occurs when the range of luminances in a visual environment is too large. Glare of this sort can have two effects: a reduction in threshold visual performance and a feeling of discomfort. Glare which reduces threshold visual performance is called disability glare. It is due to light scattered in the eye reducing the luminance contrast of the retinal image on the fovea. The magnitude of disability glare can be estimated by calculating the equivalent veiling luminance (IESNA, 2011).

The effect of disability glare on the luminance contrast of the object being looked at can be determined by adding the equivalent veiling luminance to all elements in the formulas for luminance contrast (see Section 4.6.2). Disability glare is rare in interior lighting but is common on roads at night from oncoming headlights and during the day from the sun. Usually disability glare also causes discomfort, but it is possible to have disability glare without discomfort when the glare source is large in area. This can be seen by looking at a picture hung on a wall adjacent to a window. The picture will usually be much easier to see when the eye is shielded from the window.

As for discomfort glare, this, by definition, does not cause any shift in threshold visual performance but does cause discomfort. There are many different national systems for predicting the magnitude of discomfort glare produced by interior lighting installations (IESNA, 2011; CIBSE, 2009; CIE, 2002). All these systems are based on formulas that imply that discomfort glare increases as the luminance and solid angle of the glare source increase and decreases as the luminance of the background and the deviation from the glare source increase. Lighting equipment manufacturers use these formulas to produce tabular estimates of the level of discomfort glare produced by a regular array of their luminaires for a range of standard interiors. These tables provide all the precision necessary for estimating the average level of discomfort glare likely to occur in an interior, although the precision with which they predict an individual's sense of discomfort is low (Stone and Harker, 1973).

**Shadows**  Shadows are cast when light coming from a particular direction is intercepted by an opaque object. If the object is big enough, the effect is to reduce the illuminance over a large area. This is typically the problem in industrial lighting where large pieces of machinery cast shadows in adjacent areas. The effect of these shadows can be overcome either by increasing the proportion of interreflected light by using high reflectance surfaces or by providing local lighting in the shadowed area. If the object is smaller, the shadow can be cast over a meaningful area, which in turn can cause perceptual confusion, particularly if the shadow moves. An example of this is the shadow of a hand cast on a blueprint. This problem can be reduced by increasing the interreflected light in the space or by providing local lighting which can be adjusted in position.

Although shadows can cause visual discomfort, it should be noted that they are also an essential element in revealing the form of three-dimensional objects. Techniques of display lighting are based around the idea of creating highlights and shadows to change the perceived form of the object being displayed.

The number and nature of shadows produced by a lighting installation depends on the size and number of light sources and the extent to which light is

interreflected around the space. The strongest shadow is produced from a single point source in a black room. Weak shadows are produced when the light sources are large in area and the degree of interreflection is high.

***Veiling Reflections***  Veiling reflections occur when a source of high luminance, usually a luminaire or a window, is reflected from a specularly reflecting surface, such as a glossy printed page or a display screen. The luminance of the reflected image changes the luminance contrast of the printed text or the display. The extent to which this changes visual performance can be estimated using the RVP model, but the extent to which it causes discomfort is different. Bjorset and Fredericksen (1979) have shown that a 20% reduction in luminance contrast is the limit of what is acceptable, regardless of the luminance contrast without veiling reflections (Figure 13).

The two factors that determine the magnitude of veiling reflections are the specularity of the material being viewed and the geometry between the observer, the object, and any sources of high luminance. If the object is completely diffusely reflecting, no veiling reflections occur, but if it has a specular reflection component, veiling reflections can occur. The positions where they occur are those where the incident ray corresponding to the reflected ray which reaches the observer's eye from the object comes from a source of high luminance. This means that the strength and magnitude of veiling reflections can vary dramatically within a single lighting installation (Boyce and Slater, 1981).

Like shadows, veiling reflections can also be used positively, but when they are, they are conventionally called highlights. Display lighting of specularly reflecting objects is all about producing highlights to reveal the specular nature of the surface.

### 7.3  Comfort, Performance, and Expectations

While lighting conditions that make it difficult to achieve good visual performance will almost always
**Figure 13** Luminance contrast reduction considered acceptable by 90% of observers plotted against luminance contrast of materials when no veiling reflections occurred. (after Bjorset, H. H., and Fredericksen, E. A., *Proceedings of the 19th Session of the CIE,* 1979.)

be considered uncomfortable, lighting conditions that allow a high level of visual performance may also be considered uncomfortable. Figure 14 shows the mean detection speed for finding a number from many laid out at random on a table, and the percentage of people considering the lighting good. As might be expected, increasing the illuminance on the table increases mean detection speed and the percentage considering the lighting good. However, as the illuminance exceeds 2000 lx, the percentage considering the lighting good declines even though the mean detection speed continues to increase. This result indicates that if you wish to achieve a satisfactory lighting installation it is necessary to provide lighting which allows easy visual performance and avoids discomfort and that visual discomfort is more sensitive to lighting conditions than visual performance.

There is another aspect of visual comfort which distinguishes it from visual performance. Visual performance is determined solely by the capabilities of the visual system. Visual comfort is linked to peoples' expectations. Any lighting installation which does not meet expectations may be considered uncomfortable even though visual performance is adequate; and expectations can change over time. Figure 12 also demonstrates another potential impact of visual comfort. Lighting conditions which are considered uncomfortable may influence task performance by changing motivation even when they have no effect on the stimuli presented to the visual system and hence on visual performance.

### 7.4  Approaches to Improving Visual Comfort

In order to ensure visual comfort it is necessary to ensure that the lighting allows a good level of visual performance, does not cause distraction, and allows sufficient stimulation without perceptual confusion. This can be done by

- Identifying the visual tasks to be performed and then determining the characteristics of the lighting needed to allow a high level of visual performance of the tasks (see Sections 5 and 6)
- Eliminating flicker from the lighting by using appropriate control gear for discharge and solid state lamps. If this is not possible, reduce the modulation of the flicker by mixing light from sources operating on different phases of the electricity supply
- Reducing disability glare by careful selection, placing, and aiming of luminaires so as to reduce the luminous intensity of the luminaires close to the common lines of sight
- Reducing discomfort glare by careful selection and layout of luminaires. Use the appropriate national discomfort glare system to estimate the magnitude of discomfort glare. Using high reflectance surfaces in the space will help reduce discomfort glare by increasing the background luminance against which the luminaires are seen
- Considering the density and areal extent of any shadows which are likely to occur. If shadows
**Figure 14**  Mean detection speed for locating a specified number from amongst others at different illuminances, and the percentage of observers who consider the lighting good at each illuminance. (after Muck, E., and Bodmann, H. W., *Lichttechnik*, Vol. 13, p. 502, 1961.)

are undesirable and large area shadows are likely to occur, use high reflectance surfaces in the space to increase the amount of interreflected light and use more lower-wattage lamps to supply the desired illuminance. If shadows cannot be avoided because of the extent of obstruction in the space, be prepared to provide supplementary task lighting in the shadowed areas. If dense, small area shadows occur in the immediate work area, use adjustable task lighting to moderate their impact

- Considering the extent to which veiling reflections (or highlights) are desirable. If they are undesirable, veiling reflections can be reduced by
  - Reducing the specular reflectance of the surface being viewed
  - Changing the geometry between the viewer, the surface being viewed, and the offending zone
  - Reducing the luminance of the offending zone
  - Increasing the amount of inter-reflected light in the space

## 8  INDIVIDUAL DIFFERENCES

Differences between individuals in visual capabilities are common and are usually dealt with by providing lighting which is more than adequate for visual performance and visual comfort. However, there are three sources of individual differences which are both common and consistent enough in direction to deserve special consideration. They are the effects of age, partial sight, and defective color vision.

### 8.1  Changes with Age

As the visual system ages, a number of changes in its structure and capabilities occur. Usually, the first to occur is an increase in the near point, i.e., the shortest distance at which a clear, sharp retinal image can be achieved. This increase occurs due to an increase in the rigidity of the lens with age. This change, called presbyopia, is why the majority of people over fifty have to wear glasses or contact lenses to read.

While the increasing rigidity of the lens, and other forms of focusing difficulty, can be compensated by adjusting the optical power of the eye's optical system with lenses, the other changes that occur in the eye cannot. As the visual system ages, the amount of light reaching the retina is reduced, more of the light entering the eye is scattered, and the color of the light is altered by preferential absorption of the short, visible wavelengths. The rate at which these changes occur accelerates after about sixty. The consequences of these changes with age are reduced visual acuity, reduced contrast sensitivity, reduced color discrimination, increased time taken to adapt to large and sudden changes in adaptation luminance, and increased sensitivity to glare (Boyce, 2003).

Lighting can be used to compensate for these changes, to some extent. Older people benefit from higher illuminances than are needed by young people

(Smith and Rea, 1979), but simply providing more light may not be enough. The light has to be provided in such a way that both disability and discomfort glare are carefully controlled and veiling reflections are avoided. Where elderly people are likely to be moving from a well lit area to a dark area, such as from a supermarket to a parking lot, a transition zone with a gradually reducing illuminance is desirable. Such a transition zone allows their visual system more time to make the necessary changes in adaptation.

## 8.2 Helping People with Low Vision

Low vision is a state of vision that falls between normal vision and total blindness. The World Health Organization has a system for classifying vision from normal to total blindness. Low vision occurs when the visual acuity in the better eye is less than 6/18 or the visual field is less than 10 degrees. A visual acuity of 6/18 means that the individual can just resolve details at 6 m which people with normal vision can resolve at 18 m.

While some people are born with low vision, the majority of people with low vision are elderly. Kahn and Moorhead (1973) found that among those with low vision, 20 percent reached this state between birth and 40 years, 21 percent between 41 and 60 years and 59 percent after 60 years of age. Surveys in the United States and the United Kingdom suggest that the percentages of the total population who are classified as having low vision are in the range 0.5 to 1 percent. This percentage increases markedly in less developed countries (Tielsch, 2000).

The three most common causes of low vision are cataract, macular degeneration, and glaucoma. These causes involve different parts of the eye and have different implications for how lighting might be used to help.

Cataract is an opacity developing in the lens. The effect of cataract is to absorb and scatter more light as the light passes through the lens. This change results in reduced visual acuity and reduced contrast sensitivity over the entire visual field and greater sensitivity to glare. The extent to which more light can help a person with cataract depends on the balance between absorption and scattering. More light will help overcome the increased absorption but if scattering is high, the consequent deterioration in the luminance contrast of the retinal image will reduce visual capabilities. There is really little alternative to testing the effectiveness of additional light on an individual basis. What is true for everyone with cataract is that they will be very sensitive to glare from luminaires and windows. Careful selection of luminaires and window treatments to limit glare is desirable. The use of dark backgrounds against which objects are to be seen will also help.

Macular degeneration occurs when the macular of the retina, which is just above the fovea, becomes opaque due to bleeding or atrophy. An opacity immediately in front of the fovea implies a serious reduction in visual acuity and in contrast sensitivity at high spatial frequencies. It also implies that the ability to discriminate colors will be reduced. Typically, these changes make reading difficult if not impossible.

However, peripheral vision is unaffected so the ability to find ones way around is unchanged. Providing more light, usually by way of a task light, will help people in the early stage of macular deregulation to read, although as the deterioration progresses additional light will be less effective. Increasing the size of the retinal image by magnification or by getting closer is helpful at all stages.

Glaucoma is shown by a progressive narrowing of the visual field. Glaucoma is due to an increase in intraocular pressure which damages the retina and the anterior optic nerve. Glaucoma will continue until complete blindness occurs unless the intraocular pressure is reduced. As glaucoma develops it leads to a reduction in visual field size, reduced contrast sensitivity, poor night vision, and slowed transient adaptation but the resolution of detail seen on-axis is unaffected until the final stage. Lighting has limited value in helping people in the early stages of glaucoma, because where damage has occurred the retina has been destroyed. However, consideration should be given to providing enough light for exterior lighting at night to enable the fovea to operate.

While the extent to which providing more light is helpful will depend on the specific cause of low vision, there is one approach that is generally useful. This approach is to simplify the visual environment and to make its salient details more visible. As an example, consider the problem of how to set a table so that a person with low vision can eat with confidence. The plate containing the food and the associated cutlery can be made more visible by using a contrasting tablecloth, e.g., a dark tablecloth with a white plate and cutlery. The food on the plate can be made easier to identify by using an overlarge plate so that individual food items can be separated from each other. The whole scene can be simplified can be using solid colors rather than patterns. This same approach of simplification and enhanced visibility can be applied to whole rooms, for example, by painting a door frame in a contrasting color to the door so that the door is easily identified.

## 8.3 Consequences of Defective Color Vision

About 8 percent of males and 0.5 percent of females have some form of defective color vision (McIntyre, 2002). For most activities this causes few problems, either because the exact identification of color is unnecessary or because there are other cues by which the necessary information can be obtained. Where defective color vision does become a problem is where color is the sole means used to identify significant information as, for example, in some forms of electrical wiring. People with defective color vision will have difficulty with such activities (Steward and Cole, 1989).

Where self-luminous colors are used as signals, care should be taken to restrict the range of colored lights used to those which can be distinguished by people with the most common forms of color defect. For example, the CIE has recommended areas on the CIE 1931 chromaticity diagram within which red, green, yellow, blue, and white signal lights should lie. These areas are designed so that the red signal will be named as red and the green as green by people with the most common forms of defective color vision (CIE, 1994).

## 9   OTHER EFFECTS OF LIGHT ENTERING THE EYE

Although making things visible is the most obvious effect of light entering the eye, there are two other ways in which light can affect us. The first is through the circadian system. The second is through the psychological impact of what is visible (CIE, 2009).

### 9.1   Human Circadian System

Light entering the eye does more than stimulate the visual system. It also influences the human circadian system and hence our biological rhythms. The human circadian system has three components: an internal oscillator, a number of external oscillators that entrain the internal oscillator, and a messenger hormone, melatonin, that carries the internal "time" information to all parts of the body through the bloodstream (Djik et al., 1995). The light – dark cycle is one of the most potent of the external stimuli for entrainment. By varying the amount of light exposure and when it is presented, it is possible to shift the phase of the circadian system clock, either forward or backward, as required. In addition, it is possible to have an immediate alerting effect by exposure to light during circadian night (Boyce, 2003). The amount of light required to produce phase shifts or an immediate alerting effect is within the range of current lighting practice. However, the spectral sensitivity of the circadian system is not the same as the visual system, the peak sensitivity being about 480 nm (Brainard et al., 2001; Thapan et al., 2001). This is because a different photoreceptor is used by the circadian system (Berson et al., 2002), although there is evidence that there is some interaction between the circadian photoreceptor and the visual photoreceptors (Bullough et al., 2008). This means that the effectiveness of light sources for stimulating the circadian system cannot be evaluated using the CIE photometry system (see Section 2).

The growing understanding of the importance of the light dark cycle for circadian rhythms has significance for human health and well-being. One application where exposure to light has been of interest is for shiftwork. The short term problems of shift work are fatigue, produced by poor quality sleep, and maintaining alertness during work. Long term, there is evidence that shift workers have a higher risk of cardiovascular disease, gastrointestinal ailments, and emotional and social problems. The short term problems are believed to occur because of a mismatch between the demands of the work and the state of the worker's circadian rhythm. Put plainly, the workers are expected to work when their physiology is telling them to sleep and sleep when their physiology is telling them to be awake. Light is useful in alleviating this problem because it can more rapidly shift the human circadian rhythm so that it better matches the functional requirements, but to do this requires control of light exposure for the complete twenty-four hours (Eastman et al. 1994). As for the immediate alerting affect, improvements in alertness and cognitive performance have been found following exposure to high light levels during night shift work, together with physiological changes indicative of the state of the circadian rhythm (French et al., 1990; Boyce et al., 1997).

Another human health problem that has been shown to be sensitive to light exposure is seasonal affective disorder (SAD). People with this condition typically experience decreased energy and stamina, depression, feelings of despair and a greater need for sleep during the winter months. Light therapy, in which the patient is exposed to a high illuminance for a set period each day, has been shown to alleviate these symptoms in many patients (Lam and Levitt, 1999).

The uses of light to alleviate the problems of shift work and to treat seasonal depression are just the most advanced examples of the influence of light on human well-being. Other applications of light therapy include the treatment of sleep disorders, more general, non-seasonal depression and jet lag as well as the alleviation of the fractured sleep/wake cycles of Alzheimer's patients. Also of interest is what damaging side-effects exposure to light during circadian night might have (Brainard et al., 1999; Figueiro et al., 2006). Until a clearer understanding of the positive and negative impacts of exposure to light during circadian night is achieved, it would be wise to treat attempts to use light exposure to manipulate such a fundamental part of our physiology as the circadian system with caution (Boyce, 2006).

### 9.2   Positive and Negative Affect

Psychology is a vast field and the psychology of lighting is only a small part of it. The area relevant to lighting practice that has been most consistently studied is that of perception. Studies have been undertaken in abstract situations and have lead to quantitative relations being proposed between simple sensations such as brightness and photometric measurements such as luminance (Boyce, 2003). Other studies have been undertaken in rooms with complete lighting installations and have lead to an understanding of the link between the perception of gloom and such photometric characteristics of the room as reflectance and illuminance distributions (Shepherd et al., 1989). Yet others have tried to establish if lighting generates cues by which people interpret a room, for example, does lighting the walls enhance the perception of spaciousness (Flynn et al., 1973).

While such studies have certainly influenced lighting design they cannot be said to constitute a coherent body of knowledge. Further, they cannot form a basis for lighting practice until the impacts of specific perceptions are understood. To understand the consequences of perception of lighting it is necessary to take a broader view. This view centers around positive affect. Positive affect, defined as pleasant feelings induced by commonplace events or circumstances, has been found to influence cognition and social behavior (Isen and Baron, 1991). Specifically, positive affect has been shown to increase efficiency in making some type of decisions, and to promote innovation and creative problem solving. It also changes the choices people make and the judgments they deliver. For example, it has been shown to alter peoples' preference for resolving conflict by collaboration rather

than avoidance and also to change their opinions of the tasks they perform.

Given these usually desirable outcomes of positive affect, it is necessary to ask what can generate positive affect. The answer is both small and wide. Small, because the stimuli which have been shown to generate positive affect are low-level stimuli, ranging from receiving a small but unexpected gift from a manufacturer's representative to being given positive feedback about task performance. Wide, because positive affect can be influenced by the physical environment, the organizational structure, and the organizational culture. Lighting is clearly a part of the physical environment and has been shown to influence positive affect (Baron et al., 1992; McCloughan et al., 1999) but it is only one of many factors that can do that.

As would be expected, it is also possible to generate negative affect. There is considerable information on the influence of frustration or anger on aggression and on the relationship between anxiety and performance (Baron, 1977). It seems reasonable to propose that lighting conditions that cause visual discomfort could generate negative affect.

Positive and negative affect provide plausible routes whereby the perception of the visual environment might influence the efficiency and effectiveness of organizations. As such, they represent a very different approach to identifying what is the most appropriate form of lighting for organizations to the visibility based recommendations used in lighting practice today. The possibility that improving the quality of lighting beyond that required for good visibility without discomfort would lead to enhanced organizational performance is a topic of current interest (CIE, 1998a; Boyce et al., 2006a). Somewhat encouraging for this belief is the finding that lighting perceived to be of better quality has been shown to be reliably linked to more positive feelings of health and well-being (Veitch et al., 2008).

## 10   TISSUE DAMAGE

The part of the electromagnetic spectrum from 100 nm to 1 mm is called optical radiation. This part of the electromagnetic spectrum covers ultraviolet (100–400 nm), visible (400-760 nm) and infrared radiation (760 nm–1 mm). Sunlight and electric light sources all emit optical radiation. In sufficient quantities, optical radiation can cause damage to the eye and the skin. Details are given in CIE (2006).

### 10.1   Mechanisms for Damage to Eye and Skin

There are two mechanisms for tissue damage to occur; photochemical and thermal. They are not mutually exclusive, both can occur for the same incident optical radiation but one will have a lower damage threshold than the other. Photochemical damage is related to the energy absorbed by the tissue within the repair or replacement time of the cells of the tissue. Thermal damage is determined by the magnitude and duration of the temperature rise.

The factors that determine the likelihood of tissue damage are the spectral irradiance incident on the tissue, the spectral sensitivity of the tissue, the time for which the radiation is incident and, for thermal damage, the area over which the irradiance occurs. Spectral irradiance will be determined by the spectral radiant intensity of the source of optical radiation; the spectral reflectance and/or the spectral transmittance of materials from which the optical radiation is reflected or through which it is transmitted; and the distance from the source of optical radiation. Area is important for thermal tissue damage because the potential for dissipating heat gain is greater for a small area than a large area.

The visual system provides an automatic protection from tissue damage in the eye, for all but the highest levels of visible radiation. This is the involuntary aversion response produced when viewing bright light. The response is to blink and look away, thereby reducing the duration of exposure. Of course, this involuntary response only works for sources that have a high visible radiation component, such as the sun. Sources that produce large amounts of ultraviolet and infrared radiation with little visible radiation are particularly dangerous because they do not trigger the aversion response.

### 10.2   Acute and Chronic Damage to Eye and Skin

Tissue damage can be classified according to the duration of exposure it takes to produce the damage. Acute forms of damage are detectable immediately or at least within a few hours of exposure. Chronic forms of damage only become apparent after many years.

Ultraviolet radiation incident on the skin produces an immediate pigment darkening, followed a few hours later by erythema (reddening of the skin) and, ultimately, by a tan, produced by an increase in the number, size and pigmentation of melanin granules. Excessive ultraviolet radiation incident on the eye can produce, a few hours later, an inflammation of the cornea called photokeratitis. This typically lasts a few days followed by recovery. As for chronic damage, prolonged exposure to ultraviolet radiation has been shown to be associated with various forms of skin cancer and cataract.

Visible radiation incident on the skin will produce erythema but not tanning, and, in sufficient quantity, skin burns. Visible radiation incident on the eye reaches the retina. This irradiance represents both an acute photochemical and an acute thermal hazard to the eye. Photochemical damage to the retina is associated with short wavelength light (blue light). The thermal damage covers retinal burns. As for chronic damage, it may be that prolonged and repeated exposure to light is involved in the retinal aging process.

Infrared radiation incident on the skin again initially produces skin reddening and, at a high enough irradiance, burns. Infrared radiation incident on the eye will cause heating of various elements of the eye, depending on the spectral content of the irradiance and the spectral transmittance of the various components of the eye. Infrared radiation from 760 nm to 1400 nm will reach

the retina and can cause retinal burns. Longer wavelengths will be absorbed by other components of the eye. Prolonged heating of the lens is believed to be involved in the incidence of cataract.

## 10.3   Damage Potential of Different Light Sources

The light source with the greatest potential for tissue damage is the sun. The sun produces copious amounts of ultraviolet, visible, and infrared radiation. Voluntary staring at the sun is a common cause of retinal burns. Voluntary exposure of the skin to the sun commonly produces sunburn. However, there exist some electric light sources which can be hazardous, some being intended for lighting and others being used as a source of optical radiation for industrial processes.

The extent to which a light source represents a hazard can be evaluated by applying the recommendations of the American Conference of Governmental Industrial Hygienists (ACGIH, 2009), using recommended procedures (IESNA, 2000, 2005, 2007; CIE, 1998b, 2006). These recommendations take several different forms, ranging from maximum permissible exposure times to irradiance limits. Application of these standards to various electric light sources indicates that such sources, as conventionally used for interior lighting, rarely represent a hazard (McKinlay et al., 1988; Bergman et al., 1995; Kohmoto, 1999).

## 10.4   Approaches to Limiting Damage

The approach to minimizing the damage caused by optical radiation is to limit the irradiance and/or the time of exposure. Whether any such action is necessary can be determined by applying the ACGIH recommendations to the situation.

For sources of optical radiation used for lighting, if the threshold limiting values are exceeded, it will often be possible to use a different light source that is less hazardous. If this is not possible then it is necessary to filter the source to eliminate some of the hazardous wavelengths or to use some form of eye or skin protection to attenuate the optical radiation or to limit the exposure time.

For sources of optical radiation used in industrial processes, the source should be installed in an enclosure, with an interlock so that opening the enclosure extinguishes the source. If this is not possible, then appropriate forms of eye and skin protection are required.

## 11   EPILOGUE

Illumination has been a subject of study for more than ninety years. The result has been a growing understanding of how lighting conditions and the visual system interact to facilitate visual performance and diminish visual discomfort. This knowledge has formed the framework around which many national illuminating engineering organizations have built recommendations for lighting practice (IESNA 2011; CIBSE, 2009). These recommendations provide a firm basis for designing everyday lighting installations, provided the recommendations are applied with thought and not by rote.

There are three current areas of study with considerable potential to change lighting practice:

- The value of better lighting quality for the efficiency of organizations.

  If it can be shown that better quality lighting has a reliable economic impact on organizational efficiency, the economics of lighting will be dramatically changed.

- The effect of light spectrum in mesopic conditions.

  In mesopic conditions light sources which stimulate the rod photoreceptors more produce a perception of greater brightness and allow superior off-axis performance (Rea et al, 2009; Fotios and Cheal, 2009). Such findings are likely to change both the light sources and the design recommendations for exterior lighting

- The non-visual effects of light.

  If lighting can be shown to influence the health and capabilities of people in everyday situations above and beyond allowing them to see, then the whole basis of lighting recommendations may need to be changed.

**Bradley T. Cook**
**Miller Engineering, Inc.**
**Ann Arbor, Michigan**

## 1 ABOUT THIS CHAPTER*

This chapter covers the topic of occupational safety and health management from the perspective of an ergonomics practitioner. The chapter begins by presenting a brief history of workplace safety and health issues, including the evolution of legal responsibilities of the employer. Attention then shifts to important elements of occupational safety and health. Topics addressed here include methods of classifying sources and types of occupational injury and illness, causes of accidents, and strategies for preventing or controlling accidents. Next, contemporary methods for managing occupational safety and health are discussed. These methods are primarily instituted through a workplace safety program, which carries out activities such as ensuring compliance with safety and health standards, housekeeping, accident and illness reporting and monitoring, identification and management of workplace hazards, and administering methods of hazard control. Specific occupational hazards are

---

* This chapter is a revised and expanded version of Chapter 17, "Macroergonomics of Occupational Safety and Health," in *Introduction to Human Factors and Ergonomics for Engineers*, by M. Lehto and J. Buck, Taylor and Francis, 2008.

then covered, including dangers from falls, mechanical injury, pressure hazards, electrical hazards, fire and other heat sources, toxic materials, noise hazards, and other vibration problems. The chapter concludes with a discussion of hazard communication.

## 2  INTRODUCTION

Occupational health and safety is an interdisciplinary field that focuses on preventing occupational illnesses and injuries. Government agencies, universities, insurance companies, trade associations, professional organizations, manufacturers, and service organizations all play important roles in reducing the burden of occupational illnesses and injuries to society.

Prevention efforts have paid off dramatically in industrialized countries. The annual number of accidental work deaths per 100,000 workers in the United States, as of 2008, has dropped to about one-eighth of what it was 60 years ago. Nevertheless, the accident toll continues to be high. Single events such as the BP (British Petroleum) oil rig fire and explosion in 2010 can cause multiple deaths and injuries and disrupt entire sectors of the economy, with costs mounting in tens of billions of dollars. Overall, in the United States alone, the National Safety Council (NSC, 2010) estimates that there were about 4300 accidental work deaths and 3,200,000 disabling injuries in 2008, with an associated cost of $183 billion. Major components of this cost estimate include insurance administration costs, wage and productivity losses, medical expenses, and uninsured costs. Worldwide, the direct costs of accidents are estimated to exceed several hundred billion dollars. If indirect costs are considered, such as lost productivity, uninsured damage to facilities, equipment, products, and materials, and the cost of social welfare programs for injured workers and their dependents, the bill raises to several trillion dollars annually. Consideration of pain and suffering raises the cost to an even greater level.

It also should be emphasized that, despite the fact that industrial accident rates are decreasing in most industrialized countries, economic estimates of the annual costs of accidents show the opposite trend. For example, the Liberty Mutual (2009) workplace safety index (WSI) shows an increase of 42.8% in direct U.S. worker compensation costs for the most disabling workplace injuries over the 10-year period from 1998 to 2007. Worker injuries due to overexertion, slipping, tripping, or falling alone accounted for nearly two-thirds of these costs.

The root causes of these and many other types of worker injuries and illnesses can often be addressed through better workplace ergonomics as part of an occupational safety and health program. The application of ergonomic principles to reduce workplace injuries and illnesses began years ago and continues to be a critical element of safety and health management. However, better ergonomics is only part of the solution. Many other important strategies are available that can be used by management to keep risks at an acceptable level.

An important key to success is that, instead of simply reacting to accidents, injuries, or illness, management should be proactively taking steps to prevent them from occurring in the first place.

## 3  SOME HISTORICAL BACKGROUND

Before the nineteenth century, the responsibility for occupational safety and health was placed on the individual employee. The attitude of most companies was, "Let the worker beware!"

With the advent of the industrial revolution in the nineteenth century, workplace injuries became more prevalent. Dangerous machinery caused many accidents. As manufacturing moved to larger plants, there were increasing numbers of workers per plant and an increased need for supervision. There was little theory available to guide management in reducing workplace dangers. This lack of management knowledge and an unfortunate indifference to social concerns caused many safety problems during this era.

During the mid-nineteenth century, the labor movement began as a response to worker concerns about issues such as wages, hours, and working conditions. Unions began to address safety issues. However, industrial safety did not measurably improve. Unions had limited bargaining power as well as limited knowledge about how to effectively reduce workplace hazards. Furthermore, employers did not have a strong legal incentive to improve workplace safety. During this period the law was focused on the "master–servant rule" whereby workers looked to common law to win redress. The employer was not legally obligated to provide a reasonably safe and healthful environment. Employees' actions could void employer liability if:

1.  The risks were apparent and the employee continued to work.
2.  There was some negligence by the employee.
3.  Fellow workers contributed to the injury.

Public acceptance of this situation eventually began to waiver. During the late nineteenth and early twentieth centuries there were numerous changes in the law. One was the federal Employers' Liability Act of 1908, which provided for railroad employees to receive damages for injuries due to negligence of the company or its managers, even when there was some contributory negligence on the part of the injured employee. However, the burden remained for the employee to prove the company was negligent through litigation. During this time, there were also increasing efforts by unions, companies, and trade associations to promote industrial safety. Later came "Workman's Compensation" laws enacted by individual states. These laws provided for the compensation of all injured employees at fixed monetary levels, for the most part eliminating the question of fault and the need for litigation. Most states used a casualty insurance company or a self-insurance

fund to compensate the employee for an accident under these laws. Also during this time, there were some federal government departmental efforts by the Bureau of Mines, the Bureau of Labor, and the National Bureau of Standards to improve worker safety.

Progress since the late 1930s has been impressive. During the early part of that decade, U.S. federal government actions forced management to accept unions as a bargaining agent of employees. Unions became more widespread, and safety conditions were one aspect of the contracts negotiated between employers and unions. During World War II (1939–1946), there were widespread labor shortages, which resulted in increased effort by employers to recruit and retain personnel, including a greater attention to safety for workers.

The Environmental Protection Act of 1969 secured many sources of employee protection against chemical and radiation sources in industry. In 1970 the Occupational Safety and Health Act (Williams-Steiger Act) was passed which placed an obligation on employers to provide a workplace free from recognized hazards. This act also established the Occupational Safety and Health Administration (OSHA), a federal agency whose objective is to develop and enforce workplace safety and health regulations. As shown in Table 1, a large number of laws were added over this period that directly affect worker safety and employers' responsibility toward workers. For most hazards, the enactment of laws and regulations has evolved over time with growing recognition and understanding of their nature. This tendency is illustrated in Table 2, showing how laws, regulations, and standards limiting exposure to lead have evolved over time in the United States over the past 100 years.

## 3.1 Safety And Health Achievements and Future Promises

A number of notable successes and a few failures have been observed since the passage of the Occupational Safety and Health Act of 1970 and the resulting establishment of OSHA and its sister agency, the National Institute for Occupational Safety and Health (NIOSH). One of the most notable successes is the huge reduction in the incidence of occupational poisoning. Previously, many miners were poisoned with phosphorus and many painters and printers were poisoned with lead. There has also been a decline in silicosis, silio-tuberculosis, black lung, and other associated lung diseases that principally occurred in mining but also in the manufacture of asbestos products. Some success has occurred in reducing accidents from physical fatigue and in machine safeguarding; however, several forms of guarding have created losses in productivity. Also some very unsafe factories have been closed down, but those are special cases rather than general cases of success.

Several failures have also been noted. These failures include continuing incidence of: chronic bronchitis, occupational dermatitis (which is the most common industrial occupational disability), diseases from vibration, chemical poisonings other than lead and phosphorus, lesions to bones and joints, chronic vascular

**Table 1  Timeline of Selected Laws and Acts Related to Occupational Safety in United States**

| Year | Legislation |
| --- | --- |
| 1938 | Fair Labor Standards Act |
| 1938 | Federal Product Safety and Health Legislation: Food, Drug, and Cosmetic Act |
| 1953 | Flammable Fabrics Act |
| 1958 | Longshore Safety Act |
| 1959 | Radiation Hazards Act |
| 1960 | Federal Hazardous Substances Act |
| 1966 | Federal Metal and Nonmetallic Mine Safety Act |
| 1966 | National Traffic and Motor Vehicle Safety Act |
| 1966 | Highway Safety Act |
| 1967 | Flammable Fabrics Act Amendment |
| 1968 | Radiation Control for Health and Safety Act |
| 1968 | Fire Research and Safety Act |
| 1969 | Contract Work Hours and Safety Standards Act |
| 1969 | Federal Coal Mine Health and Safety Act |
| 1969 | Environmental Protection Act |
| 1970 | Williams-Steiger Occupational Safety and Health Act |
| 1970 | Poison Prevention Packaging Act |
| 1970 | Lead-Based Paint Poison Prevention Act |
| 1970 | Other Federal Safety and Health Legislation: Clean Air Amendments |
| 1975 | Hazardous Materials Transportation Act |
| 1976 | Toxic Substances Control Act |

impairment, neuroses, and mental disorders. Several of these failures are the focus of current research.

Other ongoing changes in industry are influencing safety and health. One is that during the past two decades U. S. industry has become more capital intensive through automation. One of the positive side effects of automation is that fewer workers are exposed to some of the more hazardous occupational environments associated with tasks such as painting and welding. However, there is a downside to more capital-intensive factories and that is the requirement for greater rates of production and equipment utilization. These higher speeds are stressful mentally and apt to induce physical accidents. They are also inducements for management to cut corners.

Another phenomenon that is affecting safety and health is the enactment of equal-employment opportunity laws by the federal government prohibiting discrimination in employment based on gender, age, race, origin of birth, and religion. Employee screening, such as strength testing, conducted to ensure workers are able to perform certain jobs safely, may disproportionately eliminate older and female applicants. The Equal Employment Opportunity Commission (EEOC) requires evidence that such selection criteria are in fact necessary. Obtaining such evidence can be difficult, so many

**Table 2  Timeline of Lead-Related Regulations, Standards, and Laws in the United States**

| | |
|---|---|
| 1880–1930 | Lead, especially from paint, is suspected by health care professionals of causing deaths to children with previous symptoms of seizure, drop wrist, drop foot, etc. |
| 1910 | Marion Rhodes, a congressman from Missouri, wants to extend labeling provision of the Food and Drug Act to cans of lead paint. His bill is rejected. |
| 1930 | White House Conference on Child Health alerts participants about lead paint on toys. |
| 1930s | Paint manufacturers advise consumers of availability of lead-free paints for toys and cribs. |
| 1933 | Massachusetts — ''Revised Rules, Regulations and Recommendations Pertaining to Structural Painting'' states that ''toys, cribs, furniture and other objects with which infants may come in contact should not be painted with lead colors.'' |
| 1935 | Baltimore Health Department becomes first in nation to offer blood test for lead as a diagnostic test. |
| 1949 | Maryland state legislature passes Toxic Finishes Law, making it ''unlawful for any person to manufacture, sell or offer to sell, any toy or plaything, including children's furniture, decorated or covered with paint or any other material containing lead or other substance of a poisonous nature, from contact with which children may be injuriously affected.'' The law was repealed a year later because of ambiguities of its definitions (''injuriously''), lack of enforceability, and failure to define acceptable levels of lead for paint. |
| 1951 | Baltimore passes ordinance banning the use of paints containing lead pigments, June 29, 1951 |
| 1954 | New York City Health Department approves following label on October 29: ''Contains lead. Harmful if eaten. Do not apply on toys, furniture, or interior surfaces which might be chewed by children.'' |
| 1955 | ASA standard Z66.1 is adopted. The standard limits lead in interior paint to 1%. |
| 1958 | Baltimore mayor signs ordinance mandating warning label on paint cans: ''WARNING — Contains Lead. Harmful if Eaten. Do not apply on any interior surfaces of a dwelling, or of a place used for the care of children, or on window sills, toys, cribs, or other furniture.'' |
| 1963 | Congress passes Clean Air Act. |
| 1970 | Public Law 91-695 is enacted. It provided federal funds for mass screening, treatment, education, and research on how to lessen lead hazard. Also mandated that federally funded public housing meet the 1% paint standard. |
| 1972 | U.S. Food and Drug Administration (FDA) bans paint with an excess of 0.5 percent lead from interstate commerce under provisions of the Federal Hazardous Substances Act. |
| 1974 | Congress asks the Consumer Product Safety Commission (CPSC) to assess danger of multiple layers of paint and to determine a ''safe'' amount of lead in paint. CPSC arrives at 0.5%. |
| 1977 | CPSC adopts 0.06 recommendation of the AAP and National Academy of Sciences (NAS). |
| 1978 | National consensus is reached that lowers lead content of all household paints — interior and exterior — from 1 to 0.06%. |
| 1978 | Tetraethyl lead is removed from gasoline. |

firms prefer to reduce job requirements that require abilities that tend to differ among people by age, gender, and other bases. The Americans with Disabilities Act of 1990 further states that industry must provide access to jobs for qualified individuals with disabilities through the design of processes and workspaces to accommodate their needs when it is not economically infeasible to do so. This law puts the burden of proof for economic infeasibility on the company.

## 4  FUNDAMENTAL ELEMENTS OF OCCUPATIONAL SAFETY AND HEALTH

Much of the improvement in occupational safety and health that has been attained over the past one hundred years can be attributed to two complementary, sometimes overlapping, approaches. The first approach focuses on preventing accidents and mitigating their effects by designing safer systems and taking steps to ensure they operate as intended. The second focuses on controlling the exposure of workers to harmful substances, energy sources, or other environmental or work-related stressors that cause illnesses or cumulative trauma. The two approaches reflect the traditional dichotomy between safety and health functions still present in some organizations but have much in common. In recent years, the trend has been toward combined approaches where safety and health professionals (see Box 1) work together to identify, predict, control, and correct safety and health problems (Goetsch, 2008).

The successful application of either approach requires knowledge and understanding of:

1. Types of hazards encountered by workers and how often they result in injuries, illness, or death
2. Causes of accidents and other forms of exposure to hazards
3. Strategies for preventing or controlling accidents and exposure to hazards and their effectiveness.

<table>
<tr><td colspan="2" style="border:1px solid">

**Box 1: Safety and Health Professionals**

Many safety and health professionals are certified in particular technical specialties. The Board of Certified Safety Professionals administers the Certified Safety Professional (CSP) while the Board of Certification in Professional Ergonomics offers the Certified Professional Ergonomist (CPE) and Certified Human Factors Professional (CHFP). Certification in the practice of industrial hygiene is available from the American Board of Industrial Hygiene. Also, all of the individual states in the United States license engineers as registered professional engineers (PE). Although specific licensing in safety is not available, one of the principles of licensure is safety. The National Society of Professional Engineers has as one its fundamental canons that engineers, in the fulfillment of their professional duties, shall hold paramount the safety, health, and welfare of the public. Those working in the safety area have several professional organizations that they may join, including the American Society of Safety Engineers (ASSE) and the Human Factors and Ergonomics Society (HFES).

**Table 3 Occupations with High Incidence of Injuries in the United States 2008**

| Occupations | Number of Injuries And Illness | Incident Rate Per 100,000 Full-Time Workers |
|---|---|---|
| Laborers and freight, stock, and material movers | 79,590 | 440 |
| Heavy and tractor-trailer truck drivers | 57,700 | 362 |
| Nursing aids, orderlies, and attendants | 44,610 | 449 |
| Construction laborers | 31,310 | 383 |
| Retail salespersons | 28,900 | 90 |
| Janitors and cleaners | 28,110 | 243 |
| Light or delivery service truck drivers | 28,040 | 324 |
| General maintenance and repair workers | 20,800 | 213 |
| Registered nurses | 19,070 | 114 |
| Maids and housekeeping cleaners | 18,650 | 278 |
| Carpenters | 18,160 | 236 |
| Stock clerks and order fillers | 18,020 | 130 |

*Source*: Bureau of Labor Statistics.

As expanded upon in the following sections, classifications of occupational injuries and illnesses published by organizations such as the Bureau of Labor Statistics (BLS), NIOSH, and Centers for Disease Control and Prevention (CDC) in the United States provide a good starting point for developing understanding and perspective of particular hazards by identifying patterns of injury and illnesses, risk factors, and levels of exposure. Theories and models of accident causation build upon this perspective by identifying why accidents occur and suggesting methods of hazard control.

## 4.1 Classifications of Occupational Injuries and Illnesses

Organizations such as the BLS and NSC in the United States routinely collect and disseminate information regarding the incidence of occupational injuries and illnesses for particular occupations or industries. The rationale for following this approach is that some occupations have higher rates of certain injuries and disorders than others. Identifying such trends can guide prevention efforts by government regulators, management, and others by focusing attention on the industries and occupations with elevated incident rates. Example statistics of this type collected by the BLS are given in Table 3 for the occupations in the United States with the highest rates of injuries between 2005 and 2008.

More detailed classifications focus on particular elements of hazards, accidents, and injuries. One of the better known coding schemes of this type is the OIICS used by the BLS in the United States to code characteristics of injuries, illnesses, and fatalities. This coding scheme is used by the BLS in their annual Survey of

Occupational Injuries and Illnesses (SOII) and Census of Fatal Occupational Injuries (CFOI) programs. In the OIICS, occupational injuries or illnesses are classified in terms of the nature of injury or illness, body parts affected, primary and secondary sources of injury or illness, and the event or exposure type using a hierarchical coding scheme specified in the OIICS coding manual (http://www.bls.gov/iif/oshoiics.htm). The manual also provides selection rules and coding instructions. At the top level of the coding hierarchy, each major category (or section) is divided into one-digit codes (Table 4). The one-digit codes are then further divided into two-digit codes, and so on. For example, event code "313—Contact with overhead power lines" is a division of the broader code "31—Contact with electric current," which is a division of the even broader event code "3—Exposure to harmful substances or environments."

The source of injury or illness, with well over a thousand four-digit codes, is the largest single category of codes in the OIICS classification. The nature of injury or illness, with several hundred codes, is the second largest category, followed by event or exposure and part of body affected, both with around 300 codes. One of the advantages of the OIICS classification is that its hierarchical structure provides a systematic well-developed way of organizing the huge number of ways occupational injuries or illnesses can occur. For example, hundreds of chemicals or chemical products are systematically grouped into different subcategories within the source of injury or illness category. Patterns of occupational injury and illnesses can also be examined by examining combinations of categories,

**Table 4 Single-Digit Codes Used in Occupational Injury and Illness Classification System (OIICS) Developed by Bureau of Labor Statistics in United States**

such as cross referencing the part of body affected for a particular source of injury.

Organizations such as the BLS, NIOSH, and the NSC[*] in the United States routinely follow this approach to describe the nature of injury or illness, body parts affected, source of injury, event or exposure type, and so on, for particular occupations or industries. Other examples include the Liberty Mutual WSI mentioned

earlier which breaks out direct U.S. workers compensation costs for the most disabling workplace injuries using two-digit OIICS event or exposure codes (Table 5).

Classifications of this type guide injury prevention efforts by identifying particular groups of events (such as overexertion and falls) that can be focused upon with specific control strategies, as expanded upon in Section 6 in this chapter. However, simply identifying the event or exposure that resulted in the injury or illness tells us little about why it occurred. The latter issue has traditionally been approached by studying the causes of accidents, as expanded upon in the following section.

### 4.2 Accident Causation

Over the years, much has been learned about the causes of occupational injuries and illnesses by studying accidents. This work has led to numerous models and theories of accident causation that explain why accidents occur and also suggest generic strategies for accident prevention (Lehto and Salvendy, 1991; Goetsch, 2008).

#### 4.2.1 Early Developments

Some of the earliest research on accident causation was done by Heinrich in the 1920s. Based on his analysis of 75,000 industrial accidents, Heinrich concluded that 88% of the accidents were caused by unsafe acts, 10% by unsafe conditions, and 2% by unpreventable causes. His conclusion that 98% of accidents are potentially preventable by eliminating unsafe acts and conditions was a major departure from the prevailing opinion that industrial accidents were an unavoidable cost of progress and set the stage for a whole host of approaches for accident prevention.

Heinrich also developed what is now known as the Heinrich accident triangle, which showed that for every accident resulting in serious injury 29 resulted in minor injuries and 100 in no injury. Since serious accidents are rare events, many incidents resulting in minor or no injury are likely to occur before particular unsafe acts and conditions cause serious accidents to happen. Consequently, minor accidents and near misses can act as an early warning to an organization that serious problems

are present. The victims of serious accidents may also be unable or unwilling to tell analysts much about what caused the accident. For these and other reasons, it is now well accepted that it is important to study near misses to learn more about the causes of accidents, and many organizations, such as the Nuclear Regulatory Commission (NRC), have established policies of tracking all incidents, regardless of whether there is injury or contamination. Other examples are the Aviation Safety Reporting System (ASRS), administered by the National Aeronautics and Space Administratio (NASA), which collects voluntary safety-related reports submitted by pilots, air traffic controllers, flight attendants, mechanics, and dispatchers. Another example is the National Fire Fighter Near-Miss Reporting System, funded by the U.S. Department of Homeland Security, which collects voluntary reports submitted by fire service professionals.

### 4.2.2 Multifactor Theories

Heinrich went on to develop the domino theory, which organized the sequence of events leading to an injury in terms of five factors (or dominos): social environment and ancestry, fault of person, unsafe act or condition, accident, and finally injury. The domino theory proposed that an injury could be prevented by removing any single factor from the accident sequence. Over the years, a large number of other models and theories have been developed that build upon this basic contribution of the domino theory.

Extensions of Heinrich's early focus on the accident sequence include the development of multifactor models that show how multiple chains of events converge to cause most, if not all, accidents (Lehto and Salvendy, 1991). This approach often involves the use of event and fault trees to show how possible combinations of events and unsafe acts can come together to cause unsafe conditions, accidents, and ultimately injuries. The latter models can be used during probabilistic risk assessment to calculate the criticality of particular event sequences leading to accidents. Other approaches, including network models, such as Benner's multilinear sequencing model, flowcharts, or program evaluation review technique/critical-path method (PERT/CPM) networks, place the events and unsafe acts that lead to unsafe conditions and ultimately an accident on time lines to show both temporal and logical relationships between events and are especially useful during accident investigation to explain how and why accidents occurred.

The epidemiological model provides another useful framework for organizing the multiple factors that may play a role in accident causation. As first proposed by Gordon (1949), factors influencing accidents may be subdivided into those associated with the host (accident victim), agent (deliverer of the injury), and environment (the accident setting). The epidemiological model has guided an immense amount of accident research over the years. Extensions of this model include the industrial accident model (Johnson, 1973), which shows how characteristics of the victim, environment, and accident agent fit into the accident sequence as background factors, initiating factors, intermediate factors, immediate factors, and measurable results.

By organizing a large number of potential accident causes in a meaningful way, the model seems to have significant potential for guiding managerial efforts for reducing accidents. Another example is the Haddon matrix (Haddon, 1975), which organizes causes of traffic accidents and methods of improving traffic safety related to the driver, car, and road environment into preaccident, accident, and pos-accident stages. This framework has been used for years to guide safety programs of the National Highway Traffic Safety Administration.

Haddon (1975) also proposed 10 generic countermeasure strategies that focus on the role of energy as a cause of injury. Each countermeasure falls within different stages of the accident sequence and focuses on different elements of the epidemiological model. The strategies can be paraphrased as (1) prevent the initial buildup of energy, (2) reduce the potential energy, (3) prevent the release of the energy, (4) reduce the rate of release, (5) separate the host from the energy source, (6) place a barrier between the host and energy source, (7) absorb the energy, (8) strengthen the susceptible host, (9) move rapidly to detect and counter the release, and (10) take procedures to ameliorate the damage. The energy model serves a useful purpose in focusing attention on energy as a potential cause of accidents and can be applied in a wide variety of ways in industrial settings. The model can also be extended to generic categories of accidents involving undesired transfers or blockage of material flows. For example, the exposure to toxic materials can be viewed as a flow from some source to a susceptible host.

### 4.2.3 Human Error and Unsafe Behavior

Other models and theories have focused on the important role of human error and intentionally unsafe behavior as a cause of accidents (Lehto and Salvendy, 1991; Reason, 1990; Lehto, 2006). The role and significance of human error can be viewed from many different perspectives. At the most general level, accidents are often the predictable consequence of design errors and management oversights or omissions. Such failures include poorly designed facilities, inadequate risk assessments, safety policies, supervision, and less than adequate operating, inspection, and maintenance procedures. At the operational level, errors are often distinguished as either (1) errors of omission, such as skipping steps in critical procedures or failing to take precautions, or (2) errors of commission, such as operating a machine at the wrong speed. Errors or unsafe acts are also commonly classified in terms of their consequences, their revocability, and their detectability (Altman, 1964). Errors which have delayed consequences are often called latent errors (Reason, 1990). Latent errors and violations, such as failing to reactivate an alarm system after performing maintenance on it, are a particularly important cause of accidents, as they often are not detected or corrected until after an accident happens.

Much effort has also been directed toward determining why errors and violations occur. The overall conclusion is that a large number of performance-shaping factors can play a role, including task demands, social norms, incentives and rewards, operator objectives,

environmental factors, operator skill, and the presence or absence of feedback. One school of thought is that errors and violations are largely due to the lack of proper incentives to behave safely. This perspective is the cornerstone of behavior-based safety (Geller and Williams, 2001), a management system that focuses on developing a supportive culture in which workers receive positive reinforcement for behaving safely. A corollary to this view is that workers are sometimes rewarded for taking shortcuts or failing to follow precautions. This can result in the development of routine, or habitual, patterns of unsafe behavior such as not using personal protective equipment or not using designated pedestrian walkways. Once such patterns of behavior become engrained, it becomes difficult to eliminate them.

Flaws in human decision making (See Chapter 7 in this book) provide another explanation of why people may make poor choices leading to accidents. One issue is that measures of risk perception are sometimes poorly correlated with more objective measures such as fatality rates. People also show a general tendency to weight small, but certain, costs more heavily than large costs that are unlikely to occur. In practice, this effect corresponds to unwillingness to take a precaution that has a small cost (i.e., extra time or effort, inconvenience, or discomfort) that reduces the chance of incurring an unlikely, but serious, consequence (illness, injury, etc.). Risk compensation is another issue. For example, the benefit of modifying a forklift to make it more stable might be reduced because operators start driving faster. People also sometimes show an overreliance on safety devices and technology in general (e.g., a user might rely too heavily on an alerting system to detect a hazard). The latter tendencies are arguably rational reactions in that they are predicted by economic theory if we assume people adjust their choices to maintain an acceptable level of risk.

A large set of other modeling frameworks provide perspective into why errors occur. In particular, models of human information processing suggest that errors can be caused by lapses in attention, distractions, lack of awareness or knowledge, forgetting, time pressure, or information overload. It also can be shown that errors differ depending on the level of task performance. The latter approach has been extended by mapping preferred intervention strategies to modes of error at particular levels of task performance (Table 6). As shown in the table, several different strategies can be followed to address the root causes of errors. The following sections will address these and other strategies for preventing or controlling accidents in more detail.

### 4.3 Control Strategies

Strategies for preventing or controlling accidents and occupational exposure to hazards can be distinguished in several different ways. The most effective approaches often are focused on organizational objectives other than injury or illness prevention, such as increased reliability, quality, or productivity. Such solutions create a "win–win" situation, making it easier to gain support across the organization for their implementation. Simply put, few people would argue with the fact that

**Table 6  Error Modes and Preferred Intervention Strategies**

| Error Mode | Preferred Intervention Strategy |
| --- | --- |
| Routine behavior | *Product and Equipment Design* |
| Fail to perceive hazard condition or forgetting hazard condition — lack of situation awareness (skill based) | Hazard signals |
| | Interruptive features |
| | *Warnings* |

*Source*: Lehto (2006).

well-designed physical facilities, equipment, processes, and jobs combined with a well-trained, motivated workforce will result in higher productivity, better quality products and services, and safety.

The basic point is that efforts to improve productivity or other objectives of the organization can also lead to safety improvements. However, in many situations, additional hazard control measures are needed to attain a reasonable level of safety, such as changes in the design of facilities, equipment, processes, and jobs that in some cases conflict with productivity or other objectives of the organization. Many control measures are highly specific to particular hazards, as expanded upon in Section 6 of this chapter, which focuses on common hazards found in the workplace. The following discussion will introduce some general control strategies, beginning with job and process design. Attention will then shift to the so-called hierarchy of hazard control, which provides a way of organizing control measures.

### 4.3.1 Job and Process Design

Good job and process design can eliminate the root cause of accidents and occupational exposure to hazards in many different ways. To a large extent, this approach involves the application of techniques used in the fields of industrial engineering and ergonomics (Salvendy, 2001). Some of these approaches are as follows:

1. Principles of facility and plant layout focus on the separation of people from hazardous operations, efficient patterns of material flow which minimize the need for people to cross traffic areas, properly located and spaced aisles and walkways, and appropriate locations for exits and emergency egress.

2. Value stream mapping focuses on eliminating unnecessary movements of material from location to location, reducing forklift traffic and the need for potentially hazardous exertion while moving items.

3. Methods of production control schedule operations to help avoid ebbs and surges of activity that place excessive demands on operators to rush operations.

4. Methods of workplace layout and design help reduce unnecessary reaching, lifting, or unsafe postures.

5. Methods of task analysis can be used to systematically assess task requirements and develop appropriate solutions when they are excessive. Such solutions include providing power tools to reduce excessive exertion, training, checklists and instructions, modifying the task to make it less demanding, adding additional staff, scheduling rest breaks, and job rotation.

6. Standardization of operations, tools, and parts reduces critical confusions and errors.

7. Methods of inventory control help ensure that necessary parts, tools, and equipment are available at the time they are needed, allowing activities to be performed promptly and correctly.

8. Technical information systems help ensure that accurate updated maintenance and repair instructions, material data sheets, and other important information are made available in a timely manner when needed, which can help prevent critical errors.

9. Quality control and preventative maintenance programs help ensure that equipment and tools remain in a good state of operational readiness.

All of the above approaches address root causes of accidents. In recent years, these approaches have been repackaged in various ways. Examples include concepts such as total quality management (TQM), Six Sigma, 5S (see Box 2), the Visual Factory, Factory Physics, or lean manufacturing. Companies applying these approaches have often observed considerable improvements in both safety and productivity (Lehto and Buck, 2008). It also should be mentioned that these approaches,

---

**Box 2: 5S Programs**

As part of the so-called lean revolution in manufacturing, implementation of a 5S plus safety program (Hirano, 1996) can be viewed as a systematic approach for continuously improving safety. At the most basic level, 5S is a five-step process followed to continuously improve a selected work area, usually involving workers drawn from the particular work area selected for improvement and a 5S expert who facilitates each step of the process. The five steps in the 5S process are as follows:

$S1$ *Sort*. The first step is to take an inventory of all items currently present in the work area. This step can free up space and eliminate clutter.

$S2$ *Set in Order*. The second step is to arrange the remaining items in an orderly fashion and clearly designate a correct location for each item, which makes it obvious when something is out of place or missing. This can lead to some obvious productivity improvements by making it easier for people to quickly find things when they need them and reducing the time needed for people and materials to move around the facility.

$S3$ *Shine*. This third step, often also called "sanitize," is to carefully clean all parts of work areas and equipment and then paint them white so that dirt or grime will stand out. One of the advantages of this approach is that maintenance issues such as minor leaks in hoses and fittings become obvious long before serious problems occur. A second advantage is that the environment becomes much brighter.

$S4$. *Standardize*. The fourth step often overlaps greatly with steps 1 and 2. This follows because the number of tools, dies, fixtures, parts, and types of equipment needed for a particular process can often be reduced by standardizing processes, tools, and the products they provide to customers. This, in turn, helps reduce clutter and can greatly increase productivity.

$S5$. *Sustain*. The last step is to develop ways of sustaining the improvements that have been made. Ideally, the first four steps of 5S are made part of each worker's job so that the improvement process is continued on a permanent basis. Companies also might publicize the 5S program with a newsletter and conduct periodic 5S inspections to demonstrate commitment.

---

involving organizations such as the Purdue Regenstrief Center for Healthcare Engineering (http://www.purdue.edu/discoverypark/rche/), are currently driving major efforts in health care settings to apply methods of industrial engineering to improve patient care and safety through better delivery of critical services.

### 4.3.2 Hierarchy of Hazard Control

The so-called hierarchy of hazard control can be thought of as a simple model that prioritizes control methods

from most to least effective. One version of this model proposes the following sequence: design out the hazard, guard against the hazard, and warn (Laughery and Hammond, 1999). Another version is eliminate the hazard, contain or reduce the hazard, contain or control people, train or educate people, and warn people (Lehto and Clark, 1990). The basic idea is that designers should first consider design solutions that completely eliminate the hazard. If such solutions are technically or economically infeasible, solutions that reduce but do not eliminate the hazard should then be considered. Behavioral controls, such as training, education, warnings, employee selection, and supervision, fall in this latter category for obvious reasons. Simply put, these behaviorally oriented approaches will never completely eliminate human errors and violations.

On the other hand, few product design solutions completely eliminate human errors and violations. Furthermore, imperfect behavioral solutions can supplement and, in some cases, be preferable to product design solutions (Hoyos and Zimolong, 1988). For example, a behavioral solution that reduces the number of automobile collisions, such as enforcement of speed limits, obviously supplements design solutions such as better seat belts and is arguably acting at a more fundamental level by helping prevent the accident as well as reducing its consequences. The obvious conclusion is that designers and others need more guidance than the hierarchy of hazard control provides to select appropriate intervention strategies.

A more substantial issue is that an emphasis on nonbehavioral solutions seems to conflict with the traditional view of accident researchers that human error and intentionally unsafe behavior are the predominant cause of accidents (e.g., Cooper, 1961; Heinrich et al., 1980; Kowalsky et al., 1974; Lehto and Miller, 1986; Ramsden, 1976; Wagenaar, 1992). Part of the blame for human error can be given to poor product and equipment design (Norman, 1992). However, many other factors play a role. For example, one analysis of accidents at sea found that habits, incorrect diagnoses, lack of attention, lack of training, and unsuitable personality contributed to 93 of the 100 accidents studied (Wagenaar and Groeneweg, 1988). The authors of the latter study conclude that preventing human error is the most promising approach to reducing accidents. Some of their proposed solutions include better training, working conditions, behavioral controls, and incentives. This again supports the conclusion that behavioral solutions are an important tool in preventing accidents and deserve more consideration than the hierarchy of hazard control would suggest.

However, it should be emphasized that there are other ways of eliminating or reducing undesired behavior that can be quite effective. Some of these alternative solutions are:

1. Design for usability and understandability
2. Behavioral constraints—elements of product design that make the undesired behavior difficult or impossible

3. User selection—making the product available only to selected, qualified, and responsible users
4. Supervision, enforcement, and incentives

As pointed out by Norman (1988), human errors can often be eliminated by designing products to be more usable. Some of his suggested solutions include the use of affordances and constraints, visible and natural mappings, and the provision of feedback. Such features make correct and incorrect uses of the product more obvious to the user and reduce the need for instruction manuals, warning labels, and other types of product information.

Behavioral constraints, on the other hand, are features of the product that make it hard or impossible to perform certain behaviors (Norman, 1988). Examples include features such as interlocks, lock-ins, lock-outs, guards, or barriers. Other behavioral constraints require that the user have certain knowledge (such as a password) to operate the product and are often targeted to prevent use of a product by unqualified users. For example, consider the case of child-resistant caps. Some related strategies include screening out employees with alcohol or drug dependence or bad driving records or who have not taken training courses. Supervision- and enforcement-related strategies focus on detecting and stopping the behavior, as illustrated by the need for supervisors to detect and prevent willful violations of safety rules.

Behavioral incentives include methods of rewarding safe behavior, such as reduced insurance premiums to nonsmokers or to drivers who use seatbelts. Other uses of incentives include punishment, such as issuing tickets for failing to wear a seatbelt. At this point, it should almost be unnecessary to state that there are many fundamentally different approaches to modifying human behavior that will often be effective. Behavioral controls such as safety information supplement product design by making certain hazards more obvious. They can also supplement supervision, enforcement, and use of behavioral incentives by reminding or informing people such programs are in place. A warning sign that informs drivers that they have entered a radar speed control zone or that speeding penalties are doubled in highway construction work zones illustrates this role. A closely related role of a warning is that of providing feedback that informs the user when they make errors. The importance of the alerting and feedback roles of a warning implies that warning systems that detect and selectively respond to intermittent hazards are especially desirable.

Warnings and other forms of safety information, such as safety precautions, can also serve as performance aids that help people decide what to do (Lehto and Miller, 1986; Lehto, 1992). In the latter role, the information sources often are serving as concise forms of external memory that help people remember and apply what they already know. This can happen in at least three different ways. That is, safety information can identify or describe the hazard, describe actions that should be taken to reduce the hazard or its effects, or direct the person's attention to other sources of information. For

example, a warning label might inform the user that a product contains hydrochloric acid, briefly describe what to do if it enters a person's eye, and direct the user to the material safety data sheets (MSDSs) and other sources of more detailed information. Such information can be a useful supplement to training, instruction manuals, education, and experience. This role is especially likely to be important when people do not know or have forgotten how to perform certain safety-critical tasks.

## 4.4 Risk Management and Systems Safety

In any organization it is essential that risks be kept to an acceptable level. Rather than simply reacting to accidents, management should be proactively taking steps to prevent them from occurring. To do this properly, management must balance the severity and likelihood of the hazards faced against the effectiveness and cost of control measures. The first step in this process is to systematically identify which hazards are potentially present. The next step is to assess the criticality of each hazard on some type of risk index that takes into account both severity and likelihood. Management can then use this information to prioritize hazards and decide upon control measures that keep risks at an acceptable level.

Practitioners in the field of systems safety apply this proactive approach throughout the life cycle of a product, program, or activity (Roland and Moriarty, 1990). This process involves hazard analyses, design reviews, and specification of safety requirements at each stage of development as the design moves forward from an initial concept to production and deployment in the field. One advantage of this approach is that it is usually much easier and cheaper to eliminate hazards by taking steps early in the design process. Control measures added in response to accidents that occur after a design has been launched are also often less effective. The systems safety approach also requires hazard analyses and design reviews for proposed changes. This is important, as changes in systems, processes, or products can often create hazards. Change analysis (Johnson, 1973, 1980) is also a useful technique for identifying root causes of system failures and accidents after they occur.

Applications of the systems model often involve various forms of probabilistic risk assessment to evaluate the reliability of safety-critical subsystems and determine the effect of design changes and other control measures. In this approach, fault trees are used to determine which combinations of component failures and human errors of omission or commission can cause a subsystem to fail and how different subsystem failures can come together to cause unsafe conditions, accidents, and ultimately injuries. The probability of system and subsystem failures as well as accidents can then be calculated after assigning probabilities to component failures and human errors of omission or commission.

One major strength of following the systems safety approach is that it provides a "divide-and-conquer" strategy for systematically identifying management oversights and omissions that cause accidents (Johnson, 1975, 1980). Johnson used the systems approach to organize a large number of factors contributing to accidents in

MORT (the management oversight and risk tree). In its original form, MORT was a method for accident investigation (Johnson, 1975) but eventually evolved into a model of safety management that follows a systems approach to organize and address a large number of factors contributing to management oversights and omissions, including (1) failures to adequately assess risk and (2) less than adequate safety policies, (3) supervision, (4) engineering controls, and (5) standard operating, (6) inspection, and (7) maintenance procedures.

## 5 OCCUPATIONAL HEALTH AND SAFETY MANAGEMENT PROGRAMS

As stated in the Occupational Health and Safety Act, employers are required to provide a workplace free from recognized hazards. This is normally done by establishing a health and safety management program. Guidance on how to do this is available from a large set of sources. For example, the American National Standards Institute (ANSI) has developed a standard for occupational health and safety management, *ANSI/AIHA Z10-2005: American National Standard for Occupational Health and Safety Management Systems*. The standard contains seven sections: *Management Leadership* and *Employee Participation*, *Planning*, *Implementation and Operation*, *Evaluation and Corrective Action*, and *Management Review*. The standard outlines what has to be accomplished by the organization but is a "performance" standard and leaves the specific tasks to be determined by each organization for their unique circumstances.

Some of the features of successful safety management programs that have been found in studies of program effectiveness are summarized in Table 7.

Typical activities conducted in a health and safety management program include (1) ensuring compliance with safety standards and codes, (2) establishing a general housekeeping program, (3) accident and illness monitoring, (4) identifying and analyzing workplace hazards, and (5) implementing controls to reduce or eliminate hazards.

### 5.1 Compliance with Standards and Codes

An essential aspect of a health and safety management program is to determine which standards, codes, and regulations are relevant and then taking steps to ensure compliance. Many standards and codes are developed by consensual organizations and cover such topics as chemical labeling, personal protective equipment, and workplace warning signs. In addition, states develop regulations and standards which pertain to workplace safety and health.

The broadest applicable regulation in the United States is the OSHA General Requirements for all machines, [29 Code of Federal Regulations (CFR) 1910.212] In addition to the OSHA which place an obligation on employers to provide a workplace free from recognized hazards, OSHA also specifies a large set of detailed and mandatory health and safety design standards. OSHA also requires that many employers

**Table 7  Factors of Good Safety Management (Zimolong, 1997)**

| General Factor | Safety Practice Definitions |
|---|---|
| Management commitment | 1.  Safety officer holds high staff rank.<br>2.  Top officials are personally involved in safety activities; e.g., they make personal plant safety tours and give personal attention to accidental injury reports.<br>3.  High priority is given to safety in company meetings and in decisions on work operations.<br>4.  Management sets clear safety policy and goals. |
| Safety committee and safety rules | 1.  The safety committee holds regular, frequent meetings.<br>2.  Safety rules are regularly reviewed and updated in light of accident experience.<br>3.  There is evidence of management and staff compliance with rules. |
| Hazard control | 1.  There is a high level of housekeeping.<br>2.  There is orderly design / layout of work processes.<br>3.  There are good environmental qualities (ventilation, lighting, noise control).<br>4.  There is a greater number and variety of safety devices of on operating machinery. |
| Inspections and communications | 1.  There are daily worker-supervisor contacts on safety or other job matters.<br>2.  Formal inspections are made at regular, frequent intervals.<br>3.  There is a smaller span of supervisor control.<br>4.  There are numerous informal contacts between workers and top officials. |
| Accident investigations | 1.  Investigations and records are kept both on disabling (lost time) and record keeping injuries and nondisabling injuries.<br>2.  Investigations are made of property accidents and ''near misses.''<br>3.  There is regular use of reports for prompting hazard control measures. |
| Employee support | 1.  There are well-established procedures for job placement and advancement.<br>2.  There are personal counseling services.<br>3.  There are recreational facilities and programs for off-job hours. |
| Safety motivation | 1.  A humanistic approach is used in disciplining safety violators.<br>2.  Worker families are enlisted in safety promotions.<br>3.  Specially designed posters or displays are used for hazard recognition.<br>4.  Individual praise, recognition are given for safe job performance. |
| Safety training | 1.  Safety is included in new worker orientation.<br>2.  Workers are given initial and follow-up training in safe job procedures.<br>3.  Supervisors are given special safety training.<br>4.  A variety of safety training techniques (lectures, films, group discussions, simulations) are used. |
| Makeup of workforce | 1.  Workers are generally older.<br>2.  Workers generally have longer experience in their jobs.<br>3.  There are more married workers.<br>4.  There is less turnover and absenteeism in the workforce. |

implement comprehensive hazard communication programs for workers involving labeling, MSDSs, and employee training (29 CFR 1910.1200). OSHA enforces these standards by conducting inspections and imposing fines if the standards are not met. In addition, employers are required to maintain records of work-related injuries and illnesses and to prominently post both an annual summary of injury and illness and notices of noncompliance with standards.

In addition to federal OSHA regulations, 22 states have developed and operate state-run OSHA programs. Five additional states have state-run programs for public sector (state and local government) employment only. States must set job safety and health standards that are "at least as effective as" comparable federal standards. (Most states adopt standards identical to federal ones.) Additionally, states have the option to promulgate standards covering hazards not addressed by federal standards.

## 5.2  General Housekeeping and Preventative Maintenance

Good housekeeping and preventive maintenance conducted to prevent the development of unsafe work conditions is important in almost any imaginable work facility, especially important when toxic or hazardous materials are present or used in the production process. Some general requirements and elements of an adequate housekeeping and maintenance program are as follows:

1. Cleaning and maintenance should be scheduled on a frequent periodic basis to ensure dirt and clutter do not build up over time to unacceptable levels, minimize leaks from machinery, storage drums, and other sources, and ensure that air filters and ventilation systems are working properly.

2. Spilled liquids, dusts, and other objects should be immediately cleaned up using appropriate methods which do not add to the problem. In particular, toxic materials, acids, and otherwise reactive or hazardous materials should normally be neutralized or diluted before attempting to remove them.

3. Washrooms and showers should be provided to workers in dirty jobs.

4. Work and traffic areas should be clearly marked to separate them from temporary storage areas for work in progress (WIP).

5. Convenient, easily accessible locations should be designated for storing tools, parts, and other essential items used in the workplace.

6. Waste containers or other disposal devices should similarly be provided in convenient locations.

Despite the obvious benefits of following good housekeeping practices, any ergonomist with significant industrial experience will agree that many, if not most, organizations have difficulty maintaining a clean, uncluttered work environment for their employees (see Box 2). This tendency is especially true for small manufacturing faculties, but even larger organizations devoting significant efforts to housekeeping often have significant room for improvement. Part of the issue is that housekeeping is often viewed as a janitorial task, separate from the day-to-day responsibilities of most employees. Another issue is that clutter has a tendency to build up over long periods. In our experience, it is not unusual to find tools, equipment, and parts that have been sitting around unused for years, sometimes even taking up valuable space on the shop floor!

### 5.3 Accident and Illness Monitoring

The recording and reporting of work-related injuries and illnesses is another critical component of any safety management program. In most cases, this process involves some form of accident investigation. Another requirement is to post and maintain statistical records. These activities are mandated by the Occupational Health and Safety Act and help the employer evaluate the extent and severity of work-related incidents and identify patterns of occurrence that should be the focus of safety management efforts.

### 5.3.1 Accident Reporting

OSHA requires employers to submit a report of each individual incident of work-related injury or illness that meets certain criteria as well as maintain a log of all such incidents at each establishment or work site. Reportable incidents are those work-related injuries and illnesses that result in death, loss of consciousness, restricted work activity or job transfer, days away from work, or medical treatment beyond first aid. The specific information that must recorded is summarized below (OSHA Recordkeeping Handbook, http://www.osha.gov/recordkeeping/handbook/index.html).

OSHA form 301, "Injury and Illness Incident Report," is used to report a recordable workplace injury or illness to OSHA. Information must be provided on this form with regard to:

- Employee identification
- Medical treatment received
- Time of event and how long the employee had been at work
- What the employee was doing just before the incident occurred (s.a., "climbing a ladder while carrying roofing materials")
- What happened (s.a., "When ladder slipped on wet floor, worker fell 20 feet")
- What the specific injury or illness was (s.a., "strained back" or "broken wrist")
- What object/substance directly harmed the employee (s.a., "concrete floor") Whether the employee died

In addition, the same injury or illness must be recorded on OSHA form 300, "Log of Work-Related Injuries and Illnesses," which must be maintained at each work site. Each entry in the log identifies the employee and their job title, gives the date of the injury or onset of illness, describes where the event occurred, and gives a short description of the injury or illness, the parts of the body affected, and the object or substance that injured or made the person ill. The case is then classified into one of the following four categories based on outcome:

1. Death
2. Days away from work
3. Job transfer or restriction
4. Other recordable case

If applicable, the number of days away from work must be recorded as well as the number of days on job transfer or restriction. Finally, the case is classified as either an injury or one of five major types of illnesses.

Data from the form 300 log must be summarized at the end of each year on OSHA form 300A, "Summary of Work-Related Injuries and Illnesses." OSHA mandates that these summary statistics be posted at the work site, accessible for viewing by all employees, from February 1 to April 30 of the following year.

OSHA periodically visits plants to determine if they are in compliance with the law. When OSHA inspectors call, they have the right to see all of the reports/logs described above. Also, certain events will automatically trigger an OSHA visit, such as an accident resulting in a fatality.[*]

### 5.3.2 Calculation of Incidence Rates

Data submitted to OSHA can be used to calculate incidence rates for various types of injuries or illnesses.

---

[*] There is always an OSHA visit when a fatality occurs or more than six persons are injured in a single accident. At other times, OSHA targets certain industries because of an industry-wide problem and those cases can trigger visits.

An important component of an effective safety management program is to calculate and track these rates. *Incidence rates* should be tracked over time, and also compared to industry rates as a whole, in order to identify new problems in the workplace and/or progress made in preventing work-related injuries and illnesses.

An *incidence rate* is defined as the number of recordable injuries and illness occurring among a given standard number of full-time workers (usually 100 full-time workers) over a given period of time (usually one year). For example, the incidence rate of total nonfatal injury and illness cases in meatpacking plants in 2002 was 14.9 per 100 workers. This means that an average of 14.9 injuries and illnesses would occur for every 100 workers over the course of a year in a meatpacking plant.

The formula for calculating the incidence rate of injuries and illnesses per 100 workers is

$$\text{Incidence rate} = N \times (200,000/EH) \qquad (1)$$

where:

$N =$ number of reportable injuries and illnesses at an establishment during a one-year period

$EH =$ annual total number of hours worked by all employees at the establishment in a 50-week year

$200,000 =$ annual total number of hours worked by 100 workers (100 employees $\times$ 40 h/week $\times$ 50 weeks/yr)

The following example illustrates how to use this formula. Note that it is necessary in this example to annualize the number of accidents and number of hours worked by all employees at the establishment.

*Example:* If a plant experiences four accidents during a 26-week interval for their 80 employees who worked 40 h weekly, then the incidence rate is calculated as

$N = 2 \times 4$ accidents in a 26-week period

$= 8$ reportable accidents in an annual period

$EH = 80$ employees $\times$ 40 h/week $\times$ 50 weeks

$= 160,000$ total employee hours worked in 50 weeks

Incidence rate per 100 $= N \times (200,000/EH)$
employees per year

$= 8 \times (200,000/160,000)$

$= 10$

Another important statistic is the *lost-workday rate*. The lost-workday rate is defined as the number of lost workdays resulting from all recordable injuries and illness occurring among a given number of full-time workers over a given period of time. This statistic gives a measure of the severity of the injury and illness

experience of a given establishment. For example, two different establishments may have the same incidence rate of injury and illness. However, one establishment could have a higher lost-workday rate than the other for the same number of injuries/illnesses. In this way, the lost-workday rate tells us that the former establishment has a higher severity of injury/illness.

The formula for calculating the lost-workday rate per 100 workers is

$$\text{Lost-workday rate} = M \times (200,000/EH) \qquad (2)$$

where:

$M =$ number of lost workdays of employees due to reportable injuries and illnesses during a one-year period

$= N \times$ (avg. no. workdays lost per injury/illness)

*Example:* In the previous example, if the four cases average five days lost time each, then, again per 100 workers,

$\text{Lost-workday rate} = M \times (200,000/EH)$

$M = N \times (5 \text{ avg. workdays lost per injury/illness})$

$= 8 \times 5$

$= 40$ lost workdays due to reportable injuries and illnesses during a one-year period

It can be very beneficial to compare incidence and lost-workday rates for a particular company to industry averages. Note, however, that some caution must be observed when making these comparisons. While industry-wide rates are usually reported per 100 employees, in a few cases the rates are reported *per 10,000 employees*. Rates are typically reported per 10,000 employees only for incidents of low occurrence, such as certain types of illnesses. *When comparing company incidence rates to industry-wide statistics*, it is necessary to be sure whether the industry rates are reported per 100 employees or per 10,000 employees.

## 5.4 Hazard and Task Analysis

The process of identifying and classifying hazards has been recognized for many years as an important first step in injury and accident prevention. For example, over 50 years ago, Heinrich identified a generalized procedure for improved safety, which he called, "the hazard through-track." This through-track starts with a *hazard recognition phase* (Heinrich 1959). This phase includes developing knowledge about probable hazards and their relative importance. The second phase is to find and *name hazards explicitly*. Identifying the particular hazards involves analyses, surveys, inspections, and inquiries. Supervisory and investigative reports usually

form the basis of this identification. *Selection of a remedy* forms the third phase of this through-track. Some of the options here include engineering revisions of product or process, personnel adjustments or reassignments, and training, persuasion, and/or discipline. The last phase of this through-track consists of *implementing the remedy*. An important step here is to verify that the remedy is an improvement. Sometimes a postaudit is needed to verify that a remedy works.

### 5.4.1 Critical-Incident Analysis

One of the challenges of hazard and task analysis is the combinational explosion of conditions and events that occurs in a reasonably complex work environment. Whereas accident investigation can focus on "what happened" using deductive reasoning and physical evidence, hazard analysis must usually rely on inductive reasoning to determine "what can happen." The classic problem in accident analysis is that the analyst must consider how a possibly very large number of subsets of conditions and events might interact to produce unusual and undesirable results. Consequently, there often are not enough accident data to determine how likely certain types of accidents are.

The critical-incident technique (CIT) is a type of analysis that is helpful in bridging the gap between accident investigation and pure prospective hazard analysis (Flanagan, 1954). The CIT is used to gather useful information from "near misses," or accidents that almost happened. Since these events may have only lacked a single factor to result in an accident, their analysis can be as useful as investigating an actual accident.

### 5.4.2 Work Safety Analysis

A number of hazard identification techniques have emerged which focus on dividing work into sequences of subtasks which are then individually evaluated. Work safety analysis (WSA) is typical of such approaches and involves the development of a matrix in which hazards are identified for each subtask and then described in terms of causative factors and corrective actions (Suokas and Rouhiainen, 1984). To guide this process, checklists of generic accidents and their causes are provided to the analyst. The analyst also rates the probability and consequence of each hazard on five-point scales. The hazards are then ranked on a risk index obtained by multiplying the probability score by the consequence score, both before and after the corrective action.

Action error analysis (AEA) is a similar approach which also involves the division of work procedures into sequential stages (Suokas and Pyy, 1988). A matrix is then developed in which potential errors are identified for each stage and described in terms of primary consequences, secondary consequences, means of detection, and measures for prevention. As such, performing AEA is practically identical to developing the detectability/revocability/consequence (D/R/C) matrix (Altman 1964; 1967) as a way of prioritizing, in terms of importance, the human errors found during task analysis.

### 5.4.3 Human Reliability Analysis (HRA)

Several quantitative techniques have also been developed for analyzing human error. All such approaches involve task analysis. They diverge significantly, however, in the degree to which they attempt to develop quantitative measures of error. The technique for human error rate prediction (THERP) (Swain and Guttman, 1983) provides tabled estimates of human error probabilities for a limited set of tasks primarily relevant to those performed in the nuclear power industry. Application of THERP begins with human-error-related events in the system fault tree. The associated task is then divided into a sequence of elemental subtasks which are organized into an event tree. Human error probabilities are then assigned to the outcomes of each task from a tabled set of values. (The tabled values include provisions for the influence of performance-shaping factors and dependencies between subtask failures.) The probability of task failure is then calculated from the event tree. While advantageous in that it provides a quantitative measure of human error, the overall applicability of THERP to industrial tasks is severely limited by the limited set of tasks addressed.

The subjective likelihood index methodology (SLIM-MAUD) addresses this latter issue by focusing on expert judgment as a means of estimating the probability of an accident or human error (Embrey et al., 1984). The approach is based on decision-analytic methods for obtaining subjective probability estimates. It takes the format of asking experts to estimate (1) the importance of performance-shaping factors as causes of accidents or human error and (2) the degree to which each performance-shaping factor is present in the evaluated scenarios. This information is then used to develop a mathematical ordering of the likelihood of the analyzed errors.

### 5.4.4 Error Modes and Effects Analysis (EMEA)

Error modes and effects analysis (Lehto, 2006) is a systematic method for determining preferred intervention strategies for errors that might occur. The first step in EMEA is to identify and prioritize the hazards, or effects, associated with inappropriate behavior falling within particular stages of user or purchaser interaction with the product. The hazard identification stage in EMEA involves a process similar to that used in WSA of identifying inappropriate or missing responses, their frequency of occurrence, and the severity of associated hazards at the task or subtask level for different stages of interaction with a product (Lehto, 1996). Stages of interaction that might be evaluated include purchasing decisions, set-up or assembly tasks, ordinary use, troubleshooting, maintenance and repair, emergency procedures, and disposal of the product.

The second step in EMEA involves a systematic analysis of the behavioral basis of errors or violations that are occurring frequently or have severe consequences. This process involves determining potential skill, rule, knowledge, or judgment-based error modes for each of the analyzed errors or violations. For example, many purchasing decisions and ordinary

uses of a product are performed routinely at the skill- or rule-based levels. Other tasks such as assembly, troubleshooting, or maintenance are performed less often, perhaps at the knowledge-based level. The important point is that the behavior basis, or error mode, of the undesired behavior is likely to differ between users, tasks, and products. Once error modes have been determined for the analyzed errors or violations, the next step in EMEA is to consider appropriate intervention strategies, including product design features, training, job design, supervision, written procedures, checklists, or warnings.

## 6  COMMON HAZARDS AND CONTROL MEASURES

Hazards present in the work environment can have a significant effect on productivity, safety and health, worker satisfaction, and employee turnover. Dirty, cluttered, poorly organized work, traffic, and storage areas are one common problem. Other potential concerns include exposure to hazardous materials, temperature extremes, inadequate lighting, or noise levels. Addressing these issues requires knowledge of how environmental conditions impact people, assessment methods, and a toolbox of solutions. Engineering solutions which involve altering the environment are the most fundamental approach but are often expensive. Less expensive solutions include administrative controls, such as job rotation, rest breaks, and employee selection, as well as implementing better methods of housekeeping. Providing protective equipment and clothing is another potential solution in some situations (see Box 3). The following discussion will introduce some of these hazards along with methods of control.

### 6.1  Cleanliness, Clutter, and Disorder

Dirty, cluttered, or poorly organized work environments are a common unsafe condition that can lead to health problems and accidents, reduce employee morale and productivity, and reduce the quality of the products and services produced by a manufacturer or service

---

**Box 3: Personal Protective Equipment**

Personal protective equipment (PPE) is an especially important solution for common hazards present throughout a work environment, for example, PPE such as protective eyewear, protective footwear, gloves, hearing protection, uniforms or similar clothing, and hardhats. PPE can also be targeted to protect workers for specific tasks and hazards such as electrical lineman gloves, thermal protective clothing, and welding helmets. OSHA regulates PPE based on the industry, such as general industry, construction, longshoring, shipyard, and marine terminals. Types of personal equipment required by OSHA are given below (http://www.osha.gov/SLTC/personalprotectiveequipment/standards.html):

| PPE | Examples | Reference |
|---|---|---|
| Foot | Shoes/boots: steel toes/insoles; reinforced; rubber/plastic; thermal insulation; nonconductive; slip resistant; metal free; wooden soled; metatarsal instep guards; conductive; nonsparking; gaiter | 1910.136: Occupational foot protection |
| Leg | Leggings; knee pads; shin guards | |
| Body | Aprons; garments; full suits; cooling; puncture/cut-resistant clothing; high-visibility clothing; coats and smocks; coveralls; fire entry/proximity suits; rainwear; personal flotation device (PFD) | |
| Skin | Protective creams; cleaners | |
| Hand–finger–arm | Gloves/mittens; pads; finger guards and cots; wristlets; arm protectors; protective sleeves | 1910.138: Hand protection |
| Face | Shields; babbitting helmets; welding helmets (UV); acid-proof hoods; air-supplied hoods | 1910.133: Eye and face protection |
| Eyes | Safety glasses (frontal/side impact); protective goggles | 1910.133: Eye and face protection |
| Ears | Plugs; muffs | 1910.95: Occupational noise exposure |
| Head | Safety helmets or hard hats; bump caps; soft caps; hair nets and caps | 1910.135: Head protection |
| Fall | Safety belt; safety harness; lanyard; grabbing device; lifeline; fall arrestor; climbing safety systems | 1926 subpart M (construction) |
| Respiratory PPE | Self-contained (SCBA); supplied; purifying; filter | 1910.134: Respiratory protection |

provider. Some of the many ways this can happen are listed below:

1. People can slip on spilled liquids or powders or trip over small objects or clutter on the floor, resulting in serious injuries.

2. People's ability to move about their environment might be impeded by stacks of work in process (WIP) or other objects unnecessarily cluttering work or storage areas, aisles, and passageways.

3. Tools, parts, or other objects stacked on shelves or cluttering a work surface may use up much of the available space, and significantly interfere with people's ability to do their tasks as intended.

4. Dirt and grime accumulated on light fixtures, windows, walls, ceilings, and elsewhere in the facility can greatly reduce the brightness of the work environment, interfering with people's ability to perform essential visual tasks and in general creating unpleasant effect.

5. Toxic, irritating, allergenic, carcinogenic, tetragenic (potentially causing birth defects), or otherwise harmful substances may cause health problems when they contact the skin or are ingested when workers smoke or eat without first washing their hands.

6. Dusts, vapors, and gases may enter the air and be inhaled, resulting in serious health problems. They also might accumulate in significant quantities, creating fire and explosion hazards, or contaminate products that are being produced.

7. Poor sanitation might lead to the spread of disease within facilities and is a special concern in health care settings and food industries.

Other examples along these lines can be easily imagined. One traditional solution is better housekeeping and maintenance, as discussed earlier in this chapter.

## 6.2 Fall and Impact Hazards

Many accidents involve falling or being struck by a moving or falling object. Falls and impacts account for about 51% of the accidents reported by the Bureau of Labor Statistics (BLS) in 2008 for which there was a lost workday. These types of accidents are particularly common in the construction industry and are often easily preventable.

Falls often result from slipping or tripping. Wet floors are an invitation for slips and falls. Good housekeeping minimizes slip hazards, and marking wet floors alerts people to use caution. Keeping floor surfaces in good repair and clear of objects such as equipment and cords will also reduce trip hazards.

Falls from elevated work surfaces, such as stairs, ladders, and scaffolds, are also a frequent type of accident in this category. Safety harnesses and guardrails are important safety equipment for minimizing falls from elevated work surfaces. In addition, it is important that ladders, stairs, and guardrails meet OSHA and

---

**Box 4: Traffic Areas**

Standards such as military standard (MIL STD) 1452, OSHA (see 29 CFR 1910), or the Federal Aviation Administration (FAA) (HF-STD-001) contain a variety of general requirements for stairs, aisles, ramps, floors, and other traffic areas (also see Van Cott and Kincaide, 1972).

a. Aisles and work areas should not occupy the same floor space to help prevent interference and collisions

b. Providing necessary pull-outs or turning space in aisles for passage of wheelchairs or material-handling devices or equipment

c. Ensuring that adequate space is marked out and allocated for placing materials in storage or marshalling areas to eliminate interference with work or passage

d. Appropriate markings of aisles and passageways

e. Adequate clearance dimensions for aisles and passageways

f. Appropriate dimensions of stairs

g. Appropriate flooring materials free of protruding objects that might create tripping hazards

h. Eliminating obstacles that might be collided with

i. Avoiding blind corners

j. Making sure there is a connected, accessible path by which disabled users can reach most of the facility

k. Ensuring that doors do not open into corridors

l. Avoiding one-way traffic flow in aisles

m. Special requirements for emergency doors and corridors

Not all of these requirements are directly related to safety, but failure to comply with them often is an important contributing factor to accidents, such as falls and collisions involving pedestrians, forklifts, open doors, or other people.

---

architectural design standards (Box 4) (29 CFR 1910 Subpart D).

Elevated work surfaces also present dangers from falling objects on those working below. While work situations in which workers are working physically above others are unavoidable in many construction and maintenance operations, extreme care should be taken to prevent hand tools and other objects from falling on those working below. Sometimes fine mesh fencing can be placed horizontally to catch falling objects. Regardless, hard hats should be worn for protection at all times.

Less obvious, but important to preventing falls, is the screening and proper selection of employees for working in elevated workspaces. There are psychological and physiological differences among people with regard to their ability to tolerate heights. Some people are afraid of

being exposed to heights in which there are few barriers to falling or jumping. Such workers should be screened from jobs where work on elevated surfaces is required. New employees should always be accompanied by an experienced employee who can observe any adverse reactions to heights, or have a fear of falling, that might impair their safety. Also, people with colds or flu or who are recovering from those diseases often have an impaired sense of balance and therefore should not be working in situations where momentary imbalance can affect their safety. Some medications for colds are suspected of impairing the sense of balance.

### 6.3  Hazards of Mechanical Injury

Machinery or tools pose a potential for cutting, shearing, crushing, and pinching injuries when people contact sharp or moving parts.

### 6.3.1  Cutting/Shearing

Sharp cutting tools and machines are common hazards in many factories. Knives in the meatpacking industry are examples that come to mind easily, but there are numerous sharp edges in companies that make metal, glass, lumber, or ceramic products. Almost all manufacturing firms have sharp machine parts.

Powered cutting tools are a common cause of cutting and tearing accidents. Most of these tools have guards that prevent the human body from slipping into the rotating or reciprocating blades. While these guards are not infallible, removal of the guards should only be permitted in extreme situations where the job is impossible to perform with the guard in place. It is critical then that those guards be replaced immediately. The same is true for guards for shearing machines, which have been a source of many finger–hand amputations.

### 6.3.2  Crushing/Pinching

*Pinch points* are locations other than the point of operations where it is possible for the human body to get caught between moving parts of machinery. These points are particular hazards to crushing of body parts. Other causes of crushing include hitting one's finger with a hammer or getting one's hands between two heavy moving objects such as objects suspended from crane cables. Besides crushing, many of these same accidents can lead to broken bones.

The use of machine *guards* and *safety devices* can provide protection from mechanical injury accidents and is emphasized in OSHA standards for several industries (Table 8). Guards are intended to prevent any part of the human body from entering a hazardous area of the machine, while safety devices deactivate the machine when body parts are in hazardous areas. Sometimes safety devices are hooked to machine guards to prevent the machine from operating without the guards in place.

Preferred guards and safety devices work automatically, impose little or no restrictions on the operator, and are productive. Good guards should also be fail-safe and prevent the operator from bypassing or

**Table 8  OSHA Regulations for Specific Industries Addressing Mechanical Hazards**

| OSHA Regulation | Title |
| --- | --- |
| 1910.213 | Woodworking machinery requirements |
| 1910.217 | Mechanical power presses |
| 1910.219 | Mechanical power transmission apparatus |
| 1910.241-244 | Subpart P — Hand and Portable Powered Tools and Other Hand-Held Equipment |

deactivating them.[*] Some such guards totally enclose hazardous operations with limited, adjustable, or no access. Limited-access guards allow small product parts to be inserted by the operator but prevent entry of body parts. Adjustable-access guards permit changes to the openings around the hazard area in order to adapt to different sizes of product parts. Unfortunately, there is a tendency for operators to leave the guard at the maximum size opening at all times and hence deactivate much of the guard protection.

A number of other safety devices have been devised for worker protection. Optical screens, ultrasonic devices, and field sensing devices are common safety devices that are used around presses and press-brakes. Optical screens deactivate the machine whenever a light shield around the machine openings is broken. Ultrasonic devices and field sensing devices detect any intrusion of the hands into a hazard area and terminate machine operation. Screens and sensing devices may need to be supplemented with special stopping mechanisms in certain types of machines that complete a cycle even after the power is cut off.[†]

Other safety devices include two-hand control devices and pull-out devices. Two-hand control devices are really interlocks that require two control devices to be pressed[‡] before the machine activates. Pullout devices often have wrist cuffs that are connected to small cables that pull the operator's hands clear of the danger area when the machine activates. However, pullout devices often restrict movement and productivity.

Another type of protective approach is to use mechanical means to feed product units into dangerous

---

[*] There have been numerous instances of operators deactivating guards and other protective devices. Those deactivations often occur when the operators are working on incentive systems and they see a way to make more money by keeping the safety device from slowing them down. Incentive systems should not be employed when there are dangers of these kinds in the shop. Disciplinary action is also needed when a safety device is knowingly deactivated and not reported.

[†] Presses and press-brakes are examples of machine tools which frequently complete a cycle even after power is shut off. In such cases, special stopping mechanisms may be required.

[‡] The two devices are presumably depressed with separate hands. However, when the two-hand switch devices are too close, an operator can elbow one switch and depress the second with the hand on the same arm.

machines, thus creating protective distance between the person and the hazard. In addition to guards and safety devices, there is need for supervision to thoroughly train operators and remind them not to wear rings or loose clothing that can catch in the machine and cause accidents.[*] All of these efforts have resulted in fewer industrial accidents with mechanical injuries, but the rate is still unacceptably high.

Woodworking industries present some particular challenges in mechanical injury. One of the reasons is that wood is a highly variable material, and another is in the nature of power woodworking machines. In sawing operations, for example, a knot in the wood can be caught in a saw blade in a way that forces the piece of wood back out toward the operator. To prevent some of these situations, newer models of woodworking power tools have anti-kickback devices. Basically, those devices force the wooden workpiece to bind if the piece suddenly starts to move in the reverse direction. Other anti-kickback devices consist of camlike metal pieces next to the wooden workpiece that can move in one direction but will grip and dig into the workpiece when the direction of movement is reversed.

Mechanical injuries are a primary concern to ergonomic specialists involved in equipment design. A guiding principle is to design safety features that are simple and that minimally interfere with efficient operation of the equipment. Another principle is that danger points should be *labeled with an appropriate warning*.

### 6.4 Ergonomic Issues

Many injuries in the workplace are due to excessive lifting and exertion, exposure to vibration hazards, and repetitive motion. Each of these sources of injury is focused upon heavily by practitioners of ergonomics. The application of ergonomics to address these sources of injury will not be discussed here in detail because it is focused upon at length elsewhere in this book.

#### 6.4.1 Lifting and Overexertion

Workplace disorders and injuries due to lifting and overexertion accounted for 24% of the direct costs of worker compensation in 2007, making them the largest single contributor (Table 5). The overall cost estimate was $12.7 billion, demonstrating the major significance of such injuries. A number of generic control strategies have been developed for reducing the risk associated with lifting and force exertion. In particular, the NIOSH (http://www.osha.gov/dts/osta/otm/otm_vii/otm_vii_1 .html#app_vii:1_2) work practices guidelines specify a way of determining recommended weight limits for different lifting conditions. A number of computer modeling tools have also been developed by Don Chaffin and his colleagues at the University of Michigan Center for Ergonomics analyzing lifting, carrying, and

other forms of physical exertion. These programs are commercially available (i.e., information on the JACK program can be easily obtained from the Web).

#### 6.4.2 Vibration Hazards

Most power tools are vibratory in nature and those vibrations are imparted to people handling them. Chain saws, chipping hammers, jack hammers, and lawnmowers are a few that come to mind easily. These power tools tend to vibrate the operator's *hands and arms*. Also, some vehicles exhibit heavy vibration and people inside are subjected to *whole-body* vibration.

It is known that whole-body vibration can increase heart rate, oxygen uptake, and respiratory rate. In addition, whole-body vibration can produce fatigue, insomnia, headache, and "shakiness" during or shortly after exposure. However, it is unclear what the long-term effects are from exposure to whole-body vibration.

In the case of hand and arm vibrations, there tends to be a vasospastic syndrome known as *Raynaud's syndrome* or *dead fingers* (NIOSH, 1983). This circulatory disorder is usually permanent. Typically it takes several months of exposure to around 40–125 Hz vibration to occur, but there appears to be large individual differences among people relative to the onset. The two primary means of preventing or reducing the onset frequency of Raynaud's syndrome are (i) reducing the transfer of vibration from hand tools and (ii) protecting hands from extreme temperatures and direct air blast. Three ways to reduce vibration transfer from hand tools are (a) to make tool–hand contacts large and nonlocalized, (b) to dampen vibration intensities at the handles with rubber or other vibratory-dampening materials, and (c) to require operators to wear gloves, particularly those with vibration-arresting pads.

#### 6.4.3 Cumulative Trauma Disorders

Cumulative trauma disorders (CTDs) are frequently associated with certain occupational tasks and risk factors. Table 9 summarizes some typical occupational tasks and risk factors along with frequently associated CTDs. While most CTDs do not lead to life-threatening situations, they do lead to missed workdays and considerable inconvenience (NIOSH 1995).

OSHA provides ergonomic guidelines for certain industries to assist in the reduction of musculoskeletal disorders (MSDs). OSHA's resources related to ergonomic guidelines can be found at the following website: http://www.osha.gov/SLTC/ergonomics/resources .html. One common approach followed to address these issues is to perform a task analysis using checklists (see Box 5).

### 6.5 Noise Hazards

Excessive noise is a potential safety problem in vehicles and many work environments. Noise becomes a safety problem at certain levels and frequencies. The most commonly used scale is the adjusted decibel (dBA) scale. Even at low levels, noise can annoy or distract workers. At moderate levels, of 80–90 dBA, noise interferes with communication and causes hearing loss

---

[*] A number of companies appoint forklift operators or other roving operators to the additional duty of safety enforcement. As they go around the plant, it is their duty to remind anyone who is not following good safety practices to change behavior. Many people simply forget to wear safety glasses or hearing protectors, and simple reminders are good practice.

**Table 9  Typical CTDs, Associated Tasks, and Occupational Factors**

| Task Type | Occupational Safety Factor | Disorder |
|---|---|---|
| Assembling parts | Prolonged restricted posture<br>Forceful ulnar deviations<br>Thumb pressure<br>Repetitive wrist motion<br>Forearm rotation | Tension neck<br>Thoracic outlet syndrome<br>Wrist tendinitis<br>Epicondylitis |
| Manual materials handling | Heavy loads on shoulders | Thoracic outlet syndrome<br>Shoulder tendinitis |
| Packing boxes | Prolonged load on shoulders<br>Forceful ulnar deviation<br>Repetitive wrist motion | Tension neck<br>Carpal tunnel syndrome<br>DeQuervain's syndrome |
| Typing, cashiering | Static or restricted posture<br>Arms abducted or flexed<br>High-speed finger movement<br>Ulnar deviation | Tension neck<br>Thoracic outlet syndrome<br>Carpal tunnel syndrome |

*Source*: Adapted from Putz and Anderson (1988).

in susceptible people. Higher levels of noise (above 85 dBA) significantly increase the chance of hearing loss. The effects of long-term exposure to noise are cumulative and nonreversible.

According to the BLS, occupational hearing loss is the most commonly recorded occupational illness in manufacturing, accounting for one in nine recordable illnesses (NIOSH, 2010).

In the United States, the Occupational Safety and Health Act specifies allowable levels and duration of exposure to noise (Table 10). The act also requires that employers monitor noise levels, perform audiometric tests, furnish hearing protection, and maintain exposure

**Table 10  Permissible Noise Exposure**

| Duration Per Day (h) | Slow-Response Level, Adjusted Decibels (dBA) |
|---|---|
| 8 | 90 |
| 6 | 92 |
| 4 | 95 |
| 3 | 97 |
| 2 | 100 |
| 1 $\frac{1}{2}$ | 102 |
| 1 | 105 |
| $\frac{1}{2}$ | 110 |
| $\frac{1}{4}$ or less | 115 |

*Source*: OSHA 29 CFR 1910.95.

records whenever employee noise exposure equals or exceeds an 8-h time-weighted average level of 85 dBA (29 CFR 1910.95).

## 6.6  Pressure Hazards

Pressure hazards can be found in many industrial environments. There are a number of sources of highly pressurized gas around most industrial plants. Boilers are one common source. When the expansive force of an enclosed fluid exceeds the pressure vessel's strength, ruptures occur, often with explosive results and sometimes with great heat. In steam boilers, loss of water will create superheated steam with very high resulting pressures. Safety valves on most steam boilers are designed to trip at a safe upper pressure limit. While that practice reduces pressure hazards, that out-flowing steam is also a safety hazard for burns.

Unfired pressure vessels, such as portable gas cylinders, air tanks, or aerosol cans, can also explode when excessive pressure builds. A major cause of such accidents occurs when these vessels are exposed to sunlight or other heating sources. Special care must be exercised to keep these pressure vessels in cool environments. Note also that portable gas cylinders often contain liquefied gases, which themselves become dangerous if released. These cylinders should be prominently marked as to their contents. Also, these cylinders should always be secured when in use, during transport, and in storage to prevent falling and resulting rupture. When a fall causes a valve to break at the end of a cylinder, the cylinder can act like a flying missile.

Another pressure source that is common in industry is compressed air. Many industrial power hand tools, such as impact wrenches, use air pressure. Typically, a hose supplies compressed air to the hand tool. A typical source of accidents occurs when the hose accidentally uncouples from the tool and whips with great force. Long air hoses should be restrained in case of accidental uncoupling.

## 6.7  Electrical Hazards

*Shocks* and *burns* are by far the most common electrical injuries. Burns cause destruction of tissue, nerves, and muscles. Electric shocks can vary considerably in severity. Severe shocks can cause temporary nerve center paralysis along with chest muscle contractions, resulting in breathing impairment and, if prolonged, death by asphyxiation. Severe shocks can also cause *ventricular fibrillation,* in which fibers of the heart muscles begin contracting in a random uncoordinated pattern. This is one of the most serious electrical injuries because the only known treatment is defibrillation, which requires special equipment and skills to administer.

Other electrical hazards include:

1. Mechanical injuries from electrical motors
2. Fires or explosions resulting from electrical discharges in the presence of dusts and vapors
3. Falls that result from the electrical shock directly or as a result of human reaction afterward

---

**Box 5: Motion Appraisal Checklist**
Methods

| | | A | B |
|---|---|---|---|
| 1. | Are motions within the "normal" horizontal and vertical work areas? | — | — |
| 2. | Are motions restricted? | — | — |
| 3. | Are fixed locations in the proper sequence provided for tools and materials? | — | — |
| 4. | Is preorientation of tools and materials used to advantage? | — | — |
| 5. | Are materials conveyed mechanically or through gravity to the point of use? | — | — |
| 6. | Is the disposal point convenient so that the next movement can be made easily? | — | — |
| 7. | Have worker comforts been reasonably provided for: proper work height, back support, feet rests, etc.? | — | — |
| 8. | Are general working conditions suitable? Orderly? | — | — |
| 9. | Is use of the lowest practical class of motions made possible by the method? | — | — |
| 10. | Are both hands employed in useful work at most all times? | — | — |
| 11. | Are rhythmic motions used? Regular and free from sharp changes in direction? | — | — |
| 12. | Is prepositioning done in transit? | — | — |
| 13. | Is a change of control performed only when necessary? | — | — |
| 14. | Is the same method used by the operator at all times? | — | — |
| 15. | Do stops, guides, or pins aid positioning? | — | — |
| 16. | Does a holding device free hands for useful work? | — | — |
| 17. | Is effort minimized by combined tools, good mechanical leverage, or power tools? | — | — |
| 18. | Does a mechanical ejector remove finished parts? | — | — |
| 19. | Does the equipment effectively separate waste from finished parts? | — | — |
| 20. | Do safety devices eliminate all major hazards? | — | — |
| 21. | Is the foot or leg used to perform some part of the operation? | — | — |
| 22. | Are there postural restrictions that prevent direct forward viewing or cause unnatural postures? | — | — |
| 23. | Are all necessary work points visible by the operator for all realistic natural postures? | — | — |
| 24. | Can the operator both stand and sit? Can all foot pedals and hand-actuated controls be operated properly from both standing and sitting positions without reducing operator stability? | — | — |
| 25. | Are the maximum muscle-activated forces produced when the person's hands, arms, feet, or legs are nearly midway in the natural range of motion? | — | — |
| 26. | Can exertions be provided by either arm or leg when frequent repetitions are likely? | — | — |
| 27. | Are the largest appropriate muscle groups employed in the proper direction? | — | — |
| 28. | Is all the work performed below the person's heart? | — | — |

---

Electrical current flows inversely with resistance. The outer layers of human skin have a high resistance to electricity when the skin is not ruptured or wet. However, wet or broken skin loses 95% or more of its natural resistance. Typically, dry skin has about 400,000 $\Omega$ resistance, while wet skin resistance may only be 300–500 $\Omega$.

The following equation shows that current is equal to voltage divided by resistance:

$$I = E/R \qquad (3)$$

Using equation (3), one can determine that if a person contacts a 120-V circuit, current is only 0.3 mA with dry skin but 240 mA or more with wet skin.[*]

When a person comes into contact with an electrical source, current flows from source to ground. The path

of this source-to-ground flow is critical. If as little as 10 μA reaches the heart muscles, ventricular fibrillation can occur. One minute after the onset of ventricular fibrillation, the chance of survival is 99% if both a defibrillator and the people with the training to use it are available; otherwise the chances are about 1/10,000 for survival.

One cause of electrical accidents is contact with bare power conductors. Ladders, cranes, or vehicles can strike power lines and act as a conducting agent to whomever is touching it. While insulated electric wires offer some protection as long as the insulation is intact, the insulation can break down due to heat or weather or as a result of chemical or mechanical damage. As the insulation weakens, the hazard level approaches that of a bare conductor. In fact, there can be even more danger because the insulation makes the wire still appear to be safe. Insulation breakdown is often accelerated in high-voltage circuits. The corona around high-voltage wires often produces nitrous oxide, which becomes weak nitric

---

[*] Amperage $I$ = 120 V/400,000 $\Omega$ = 0.3 mA with dry skin but $I$ = 120/500 = 240 mA with wet skin.

acid in the presence of moisture; this compound further decomposes insulation.

Equipment failure is another cause of electrical accidents. Internal broken wires can sometimes ground out to the external casing of the equipment. To prevent this, manufacturers of electrical equipment have begun to provide double insulation or a direct-grounding circuit for internal wiring. In addition, ground-fault circuit interrupters are now widely used because these interrupters shut off the circuit almost instantly when the ground circuit exceeds the limit. Many building codes require ground-fault circuits in exterior electrical outlets and those in a garage.

Electrical safety can be improved by designing electrically powered equipment with several features. Most importantly, all electric-powered devices should be designed such that they can be placed in a zero-energy state (i.e., power can be shut off). An associated second feature is the ability to lock out the power via a tag, cover, or hasp and padlock. It is one thing to turn off power; it is another to make sure it stays off, particularly during service or maintenance. A third safety feature is important in power equipment that utilizes energy-storing devices such as capacitors or accumulators. Such equipment should be designed so that an operator can safely discharge the energy from these storage devices without contact.

Sometimes fires and burns can result from electrical devices overheating. Electrical heating systems are particularly prone to overheat. Circuit breakers and thermal lockouts are common devices to prevent those occurrences. These devices may have thermally activated fuses, regular circuit breakers that are thermally activated, or circuit breakers that bend with heat and open the circuit at set upper temperature limits.

Another source of electric hazard is static electricity. *Static electricity* exists when there is an excess or deficiency of electrons on a surface. That surface becomes the source or sink of a very high voltage flow,[*] particularly when the humidity is low. Static electricity occurs often in papermaking, printing, and textile manufacture. A primary danger is that dust and vapor explosions can be ignited with the static electrical discharge.[†] Static electricity can be reduced by using materials that are not prone to static buildup. Another protection is to ground out equipment so that there is no buildup of static electricity. Other prevention measures consist of neutralizing the static electricity and humidifying to reduce the buildup. Lightning is a natural discharge of static electricity. Large conductors and ground rods are used to safely ground out the discharges. Pulse suppressers are often used with computers and other equipment that are vulnerable to damage caused by power spikes, which lightning often produces.

## 6.8 Heat, Temperature, and Fire Hazards

### 6.8.1 Heat/Temperature Hazards

While most industrial hazards in this category are heat related, it should be remembered that very low temperatures associated with freezing[‡] or with cryogenic processes can also be a source of danger.

Burns are the principal result of accidents involving heat. The severity of a burn depends upon the temperature of the heat source and the duration and region of the contact. Milder burns, which usually only redden the skin, are *first-degree* burns. *Second-degree* burns are more serious and are usually associated with blisters on the burned areas of the skin. When the blisters break, there is a chance of infection. The most severe type of burns are *third-degree* burns, which penetrate all the layers of the skin and kill nerve endings. Third-degree burns can cause the affected tissue to appear white, red, or even a charred grey or black. Typically part of the tissue, capillaries, and muscle are destroyed, and gangrene often follows. Freezing burns are similar to heat burns in many ways, including the degrees of severity.

### 6.8.2 Ultraviolet Radiation Hazards

Ultraviolet (UV) radiation can also cause burns. Eyes are particularly vulnerable to UV burns, as eyes are much more sensitive to UV radiation than the skin. UV radiation is emitted during welding, so special eye protection must be worn to protect the welder's eyes. UV rays can also bounce off light-colored walls and pose a hazard to others in the vicinity. For that reason, welding booths are recommended. Other types of equipment that pose similar hazards include drying ovens, lasers, and radars.

### 6.8.3 Fire Hazards

A fire requires three principal elements. These are:

1. Fuel (or reducing agent), which gives up an electron to an oxidizer
2. Oxidizer, which is the substance that acquires the electrons from the fuel
3. Source of ignition, which is anything capable of commencing the oxidation reduction reaction to a sufficient degree for heat or flame

Many substances are always fuels or always oxidizers, but a few will switch roles.[§] Fuels include regular heating fuels, solvents, and any other flammable liquids, gases, or solids.[¶] Oxidizers include oxygen itself and compounds carrying oxygen.[‖]

---

[*] Typically, the static electical flow has very low amperage but extremely high voltage.

[†] In the late 1970s R. R. Donneley Company had a plant in Chicago explode due to static electricity. Paper dust in the overhead trusses was ignited by the static electricity caused by moving paper in the machines.

[‡] Freezing is associated with food processing.

[§] Sometimes a substance can be either a fuel or an oxidizer, depending upon what the other substance is.

[¶] Other examples of fuels are fuels for internal combustion engines or rocket engines, cleaning agents, lubricants, paints, lacquers, waxes, refrigerants, insecticides, plastics and polymers, hydraulic fluids, and products of wood, cloth, paper, or rubber and some metals, particularly as fine powders.

[‖] Other examples of oxidizers are halogen, nitrates, nitrites, peroxides, strong acids, potassium permanganate, and fluorine gas, which is even stronger than pure oxygen.

**Table 11 Flammability Properties for Selected Compounds**

| Compound | Lower Flammability Limit (LFL, %) | Upper Flammability Limit (UFL, %) | Flash Point ($^\circ$C/$^\circ$F) | Auto-Ignition ($^\circ$C/$^\circ$F) |
|---|---|---|---|---|
| Ethanol | 3.0–3.3 | 19 | 12.8 55 | 365/689 |
| Methanol | 6.0–6.7 | 36 | 11.0/52 | 385/725 |
| Methane | 4.5–5.0 | 15–17 | Flammable Gas | 580/1076 |
| Mineral spirits | 0.7 | 6.5 | 38–43/100–109 | 258/496 |
| Gasoline (100 octane) | 1.4 | 7.6 | <−40−40 | 24–280/475–536 |
| Kerosene Jet A-1 | 0.6–0.7 | 4.9–5 | >38/100 as jet fuel | 210/410 |

The key to prevention and control is *keeping these three parts separated in time and/or space*. Airborne gases, vapors, fumes, or dusts are particularly dangerous, since they can travel significant distances to reach ignition sources and often burn explosively.

A flammable material can be a gas, liquid, or solid. Flammable gases burn directly. In contrast to gases, liquids do not burn; they vaporize and their vapors burn. Solids often go through two phase changes before burning, first to liquid and then to gas, but that does not always hold. When the solid is in the form of a fine dust, it becomes much more flammable and even explosive.

Many gases are flammable in the presence of air when there is a sufficient concentration. The lower flammability limit (LFL) of a gas is the lowest concentration of the gas in air that will propagate a flame from an ignition source; below that it is too dilute. The upper flammability limit (UFL) is the highest concentration of a flammable gas in air that will propagate a flame from an ignition source; above that the concentration is too rich to burn. Both of these limits are measured as the percentage of gas by volume. Generally the wider the difference between the UFL and LFL, the greater the range of burning conditions and the more dangerous the substance (Table 11).

Flammable liquids burn when they vaporize and their vapors burn. Several variables affect the rate of vaporization, including the temperature of the liquid, latent heat of vaporization, size of exposed surface, and air velocity over the liquid. The f*lash point* is the lowest temperature at which a liquid has sufficient vapor pressure to form an ignitable mixture with air near the surface of the liquid. The lower the flash point, the easier it is to ignite the material. Note that this term is distinctive from the *fire point,*[*] which is the lowest temperature that will sustain a continuous flame. The fire point is usually a few degrees above the flash point. Clearly, the lower these critical temperatures are, the more sensitive that substance is to burning.

A liquid is classified as *flammable, combustible*, or *nonflammable* based on its flash point. A liquid is flammable if its flash point is below a specified temperature and combustible if its flash point is above this level but below a higher specified level (and so somewhat harder to ignite). Liquids with a flash point above the higher limit (and so most difficult to ignite)

are classified as nonflammable. Different organizations and agencies use different specified limits for these classifications.

Another term of significance to fires is the *autoignition temperature,*[†] which is the lowest temperature at which a material (solid, liquid, or gas) will spontaneously ignite (catch fire) without an external spark or flame. Most organic materials contain the mechanisms for autoignition, which is also referred to as *spontaneous combustion*. Lower grades of coal are volatile and may self-ignite if temperatures build up sufficiently high. Hay, wood shaving, and straw undergo organic decomposition that creates heat internally and may cause self-ignition. Oily rags are particularly dangerous because of the large exposed area to air. When these rags are in a pile, the outer rags insulate those in the center and hold the buildup of heat there. Also, oily insulation around steam lines and heat ducts is another source of self-ignition. *Hypergolic reactions* are special cases of self-ignition where the fuel and oxidizer combust at room temperatures upon mixing. Some of the substances known for hypergolic reactions are white phosphorus, some hydrides, and many iron sulfides that are common wastes in mineral processing or oil fractionation.

Fires inside buildings often have poor ventilation so there is incomplete combustion, which in turn produces carbon monoxide. Carbon monoxide is both toxic and flammable. It is the toxicity of the carbon monoxide more than the smothering effects of carbon dioxide and smoke that is responsible for the highest percentage of fire-connected fatalities. Also carbon monoxide tends to reignite as more ventilation improves the combustion mixture. It is this reignition that results in explosions that frequently occur as fire fighters break windows or holes in the side of a burning building. Toxic conditions of carbon monoxide occur at as low a concentration as 1.28% for a 3 min duration.

Fire-extinguishing methods are specific to the type of fire. Class A fires involve solids that produce glowing embers. Water is the most common fire extinguishing recommended for this class of fires. However, water is *not* recommended for other classes of fires except as a spray alone or with special additives. Class B fires involve gases and liquids such as automotive fuels, greases, or paints. Recommended extinguishants of this class of fires are bromotrifluoromethane, carbon dioxide,

---

[*] A term that is equivalent to fire point is *kindling temperature*.

[†] Spontaneous ignition temperature or combustion temperature has the same meaning as autoignition temperature.

dry chemical foam, and loaded steam. The administration of water to class B fires often spreads the fire. Class C fires are class A or B fires which involve electrical equipment. In this case, recommended extinguishants are bromotrifluoromethane, carbon dioxide, and dry chemical. Care should be taken in class C fires not to use metallic applicators that could conduct electrical current. Finally, class D fires consist of combusting metals, usually magnesium, titanium, zirconium, sodium, and potassium. Temperatures in this class of fires tend to be much greater than in the other classes. There is no general extinguishant for this class of fire, but specific extinguishants are recommended for each type of metal.

One of the best strategies to protect against fires is, of course, to prevent their occurrence by keeping separate the elements that make up fires. A second strategy is early detection. Of course, different detection systems are based on different features that accompany fires. Some detectors have bimetallic strips that expand with a sufficient rise in temperatures to close an alarm circuit. Similar kinds of detectors enclose a fluid that expands under heat until a pressure-sensitive switch is activated. Thermoconductive detectors, another variety, contain insulation between conductor wires. As the heat rises, the insulation value of this special material decreases to a sufficient extent that electrical power flows through that material, creating a new circuit that sets off the alarm. Accompanying the heat of a fire are infrared rays. Thus, infrared photoelectric cells are used in radiant energy detectors. Another form of detector is one based on light interference. These detectors have a glass or plastic tube, through which the air flows, and there is a light source on one side of the tube and a photoelectric cell on the other. When smoke comes from a fire into the tube, the light is refracted from the photoelectric cell and an alarm sounds. Finally, there are ionization detectors that measure changes in the ionization level. Byproducts of combustion cause the air to become ionized, which in turn activates these detectors.

## 6.9  Hazards of Toxic Materials

*Toxic materials* are poisons to most people, meaning that small quantities will cause injury in the average person. Those substances that only affect a small percentage of the population are *allergens.* Toxic substances are typically classified as:

1.  Irritants if they tend to inflame the skin or the respiratory track
2.  Systemic poisons when they damage internal organs
3.  Depressants if they act on the central nervous system
4.  Asphyxiates if they prevent oxygen from reaching the body cells
5.  Carcinogens if they cause cancer
6.  Teratogens if they affect the fetus
7.  Mutagens if the chromosomes of either males or females are affected

A number of substances are well-known *irritants*. Ammonia gas combines with moisture of mucous membranes in the respiratory tract to form ammonium hydroxide, which is a strong caustic agent that causes irritation. Acid baths in plating operations often use chromic acid that not only irritates but also eats holes in the nasal septum. Most of the halogens, including chlorine and phosgene, are strong irritants. Chlorinated hydrocarbon solvents and some refrigerants are converted to phosgene when exposed to open flames. Dusts of various origins[*] inflame the respiratory tract of most people and can cause pneumoconiosis. Long-term exposure to some dusts, even to low concentrations, can result in permanent damage to the health such as lung scarring.

*Systemic poisons* are far more dangerous than irritants. Lead poisoning from paint has been a well-publicized problem. Other metals, such as cadmium and mercury, and some chlorinated hydrocarbons and methyl alcohol, which are used as solvents and degreasing agents, are not as-well-known poisons.

There are a number of substances that are *depressants* or narcotics to the nervous system. While the effects of many are only temporary, depressants pose strong safety hazards because they interfere with human judgment. Best known as a depressant is ethanol, also known as ethyl alcohol, whose impairments to judgment and control are clear. Other depressants include acetylene (used in welding), as well as methanol and benzene, both of which are popular solvents. In addition to being depressants, methanol and benzene are also systemic poisons, while benzene is also a carcinogen (i.e., leukemia).

*Simple asphyxiates* are gases that displace inhaled oxygen, which in turn reduces the oxygen available in the human body. One simple asphyxiate is methane, which is a by-product of fermentation. Other simple asphyxiates include argon, helium, and nitrogen, which are used in welding, as well as carbon dioxide, which has numerous industrial uses and is a byproduct of complete combustion. Problems arise with simple asphyxiates when people must work in closed spaces with large concentrations of these gases. More insidious are the *chemical asphyxiates* that interfere directly with oxygenation of the blood in the lungs and thereby create oxygen deficiencies. One of the best known chemical asphyxiates is carbon monoxide, which is the by-product of incomplete combustion and is typically associated with exhausts of internal combustion engines. This gas has an affinity for hemoglobin that is over 200 times stronger than oxygen and is known as the cause of many deaths. The industrial insecticide hydrogen cyanide is another very dangerous chemical asphyxiate.

*Carcinogenic* substances are in the news frequently, but the degree of danger of these substances varies greatly. As mentioned above, lead is a carcinogen. Another carcinogen is vinyl chloride. Vinyl chloride is extremely dangerous in other ways as it is flammable, giving off phosgene when burning, and it is explosive.

---

[*] Asbestos fibers, silica, and iron oxide are examples of irritants commonly found in industry.

Extreme care must to be exercised in handling these carcinogenic compounds as well as those that are *teratogens* or *mutagens*.

Guidance regarding dangerous substances is available from many sources. OSHA and the U.S. Environmental Protection Agency (EPA) both publish lists of products that should display warnings of danger (29 CFR 1910 Subpart Z). These lists also carry the Chemical Abstracts Service (CAS) identifier numbers to help clarify chemicals with multiple names. However, these lists are very long and some firms are using expert systems and other computer systems to identify these chemical hazards and the various limits of permissible exposure.

### 6.9.1 Measures of Exposure and Exposure Limits

One measure of substance toxicity is the *threshold limit value* (TLV). A TLV is the maximum allowable concentration of a substance to which a person should be exposed; exposures to higher concentrations are hazardous. TLVs are used primarily with reference to airborne contaminants that reach the human body through the respiratory system.

Published TLVs indicate the average airborne concentration that can be tolerated by an average person during exposure for a 40-h week continually over a normal working lifetime. These values are published periodically. As new information becomes available, the American Conference of Governmental Industrial Hygienists (ACGIH, 2010) reviews this information and sometimes changes the TLVs. Therefore, TLVs are usually stated as of certain dates of publication. It should also be stated that the TLVs issued by ACGIH are *indicators* of relative toxicity. The actual danger depends upon other things as well, such as volatility, because more volatile substances generate more gas exposure. OSHA reviews the ACGIH publications of TLVs and may or may not accept those limits. Then OSHA publishes its *permissible exposure limits* (PELs), a term used to distinguish OSHA's exposure limits from consensus standards by ACGIH or any other noted group. PELs and TLVs are highly correlated but not always identical. Many firms adopt the most restrictive limits. Note that some states publish more restrictive limits than those published by OSHA.

TLVs (and PELs) are generally expressed in milligrams per cubic meter. If a substance exists as a gas or vapor at normal room temperature and pressure, its TLV (or PEL) can also be expressed in parts per million (ppm). The relationship between concentrations expressed in units of milligrams per cubic meter and those expressed in units of parts per million (at 25°C and 1 atm of pressure) is

$$\text{TLV (ppm)} = \frac{24.45 \times \text{TLV(mg/m}^3)}{\text{gram molecular weight of substance}} \quad (4)$$

For a few substances, such as asbestos, the TLV (or PEL) is stated in terms of units, or fibers, per cubic centimeter.

Exposure can be measured at a single point in time or as a weighted average over a period of time. TLV and PEL values are generally stated as 8-h *time-weighted averages* (TWAs). An 8-h TWA exposure is computed as

$$\text{TWA} = [C_1 T_1 + C_2 T_2 + \cdots + C_n T_n]/8 \quad (5)$$

where:

  TWA = equivalent 8-h TWA concentration
   $C_i$ = observed concentration in time period $i$
   $T_i$ = duration of time period $i$ in hours
   $n$ = number of time periods studied

When a person is exposed to a single kind of substance hazard, one merely inputs the concentration and time data in the above equation and compares the answer with the PEL corresponding to that substance. If the computed TWA is less than the PEL, then conditions appear moderately safe and the legal requirements are met.

On the other hand, if there is exposure to multiple hazards, then a mixture exposure should be computed as

$$E_m = [C_1/L_1] + [C_2/L_2] + \cdots + [Cm/Lm]$$

where:

  $E_m$ = equivalent ratio for entire mixture
  $C_j$ = concentration of substance $j$
  $L_j$ = PEL of substance $j$
  $m$ = number of different contaminants present in the atmosphere

Safe mixtures occur when $E_m$ is less than *unity*. Even when the exposure to individual substances in a mixture is below each relevant PEL value, the mixture ratio can exceed unity and hence be dangerous; this is more likely as more substances are involved.

There are a number of different ways of finding the concentrations of various substances. Most typically, samples are taken at the site and these bottled samples or special filters are taken to a laboratory for analysis. For certain substances, there are direct-reading instruments that can be used. In addition, for some substances dosimeters are available, which can be worn by employees to alert them when they are in the presence of dangerous exposure levels. Miners frequently use dosimeters for the most common contaminants in mines and people around radioactive materials constantly wear radiation dosimeters on the job.

Additionally, TLVs can also be expressed as *short-term exposure limit* (STEL) or *Emergency exposure limits* (EELs). The STEL denotes the maximum acceptable concentration for a short specified duration of exposure, usually 15 min. These STEL measures are intended for people who are only occasionally exposed to toxic substances. EELs have been introduced more recently and indicate the approximate duration of time a person can

**Table 12  Selected PELs and TLVs from OSHA Chemical Sampling Information File (2010)**

| Substance | CAS No. | PEL mg/m3 | PEL ppm | TLV ppm (TWA) | TLV ppm (STEL)[a] |
|---|---|---|---|---|---|
| Acetic acid | 64-19-7 | 25 | 10 | 10 | 15 |
| Ammonia | 7664-41-7 | 35 | 50 | 25 | 35 |
| Asbestos | 1332-21-4 | 0.1 fiber/cm$^3$ | — | — | 0.1 fiber/cm$^3$ |
| Bromine | 7726-95-6 | 0.7 | 0.1 | 0.1 | 0.2 |
| Carbon dioxide | 124-38-9 | 9000 | 5000 | 5000 | 30,000 |
| Carbon disulfide | 75-15-0 | — | 20 | — | 10 |
| Carbon monoxide | 630-08-0 | 55 | 50 | 25 | — |
| Ethanol | 64-17-5 | 1900 | 1000 | — | — |
| Fluorine | 7782-41-4 | 0.2 | 0.1 | 1 | 2 |
| Furfuryl alcohol | 98-00-0 | 200 | 50 | 10 | 15 |
| Hydrogen cyanide | 74-90-8 | 11 | 10 | — | 4.7 |
| Methyl alcohol | 67-56-1 | 260 | 200 | 200 | 250 |
| Nitric acid | 7697-37-2 | 5 | 2 | 2 | 4 |
| Pentane | 109-66-0 | 2950 | 1000 | 600 | — |
| Phenol | 108-95-2 | 19 | 5 | 5 | — |
| Propane | 74-98-6 | 1800 | 1000 | 2500 | — |
| Stoddard's solvent | 8052-41-3 | 2900 | 500 | 100 | — |
| Sulfur dioxide | 7446-09-5 | 13 | 5 | — | 0.25 |
| Uranium soluble | 7440-61-1 | 0.05 | — | — | — |

[a]STELs are generally set by the ACGIH, not OSHA, and should be compared to TLVs.

be exposed to specified concentrations without ill effect. EELs are important for personnel who work with toxic substance problems.

Table 12 presents some of these limits for a few selected common substances. This table is presented for illustrative purposes only; PELs, TLVs, and STELs are updated regularly and can be found on the OSHA website.

### 6.9.2  Protection from Airborne Contaminants

*Ventilation* is the most common control strategy used for airborne contaminants. The idea is to remove the substance from the air before it reaches people. Ventilating systems are typically designed by mechanical engineers who specialize in this application. An effective ventilating system consists of a contaminant collector, properly sized ductwork laid out to allow smooth airflow from the source to the collector, and exhaust fans which maintain a near-constant negative pressure throughout the system. A number of different types of collectors are used depending upon the substance. Low-pressure cyclone collectors are often used for large particles and sawdust. Electrostatic precipitators, wet-type dust collectors, scrubbers, and fabric collectors are other forms of collectors used for different types of substances.

*Personal protection devices* are also used to protect people from airborne contaminants. Respirators with filters are commonly used in places where there is a lot of dust or vapor that can be neutralized by a chemical filter. Some types of respirators receive air from a compressor much like a diver in the sea. In addition to the respiratory tract, the skin must also be protected. Suits made of special fabrics are frequently used to protect the skin along with gloves for the hands.

*Emergency response* and *cleanup* are other important issues that arises in the use of chemicals and potentially hazardous substances (Box 6).

### 6.10  Transportation Hazards

Transportation-related accidents are the leading cause of occupational deaths (40%). Transportation safety requirements generally fall outside the jurisdiction of OSHA and are controlled by other governmental agencies such as the Department of Transportation (DOT), FAA, and Federal Railroad Administration (FRA).

The most effective means to control transportation hazards is the use of mandated safety features, such as those required by standards/regulations (DOT, FMVSS, SAE). Training employees to properly use modern vehicle safety features (bumpers, side-impact systems, active and passive passenger restraints, etc.) coupled with roadway safety features (signage, traffic lights, lane markings, traffic separation devices, etc.) can be effective in minimizing transportation hazards.

Transportation hazardous can also be related to the cargo being transported. Common hazards from cargo faced when transporting it include materials that are explosive, flammable/combustible, radioactive, oxidizing/corrosive, poison, and etiologic. Controls of hazards related to cargo include excluding materials, limiting quantities, defining storage rules, packaging design and selection, labeling, restricting transportation routes, and training. In addition, the U.S. DOT regulates the transportation of many of these items that have hazards discussed above.

---

**Box 6: Hazardous Waste Operations and Emergency Response (HazWOpER), 29 CFR 1910.120 (1987)**

HazWOpER applies to employers and employees engaged in hazardous substance response and cleanup operations; operations involving hazardous waste storage, disposal, and treatment; operations at sites designated for cleanup; and emergency operations for release of hazardous substances. A HazWOpER plan contains the following elements:

*Site Characterization*. Identify conditions that might be immediately dangerous to life or health and determine appropriate safety and health control measures needed to protect employees.

*Site Control*. Prevent contamination of employees by designating work zones, operating procedures, communication, and medical assistance.

*Training*. Provide hazard and procedure information to employees with 40 h off-site and three days under supervision on-site leading to certification. Define names of responsible personnel, hazards present, signs and symptoms of overexposure, use of engineering controls and equipment, work practices, and PPE.

*Medical Surveillance*. Monitor employees exposed to hazards, including potential exposure and respirator use for at least 30 days/year. This required a medical examination and consultation with a licensed examining physician, informing employee with written opinion of physician, and recordkeeping of above.

*Controls*. Design engineering controls or work practices and ensure effective use of PPE. PPE program must address hazards, task duration, in-use monitoring, and decontamination.

*Monitoring*. Monitor hazards for identification and control purposes.

*Informational*. Inform employees of plan addressing hazards. Requires formal, written, site-available plan, including information on names of key or responsible personnel, task safety analysis, training assignments, PPE, medical surveillance/monitoring plans, control measures/contingency plans, decontamination procedures, and confined-space entry procedures.

*Material Handling*. Set standards for the handling of containers of hazardous materials and wastes.

*Decontamination*. Requires decontamination procedures (employees, clothing, equipment, site), exposure control, communication, assessment, and improvement.

*Emergency Response*. Requires preemergency planning, delineation of responsibilities, recognition and prevention, safe distances and refuge, site security and control, evacuation/decontamination, emergency medical treatment/first aid, PPE and emergency equipment, and evaluation.

*Illumination*. Adequate lighting during associated tasks requires a minimum of 5 footcandles (fc) general, 10 fc in general shops, 30 fc in offices, first aid/medical areas.

*Sanitation*. Requires adequate supply of potable water on-site, identification of nonpotable water supplies, toilet facilities, and, if provided, food, sleeping, and washing facilities in compliance with law.

---

## 7 HAZARD COMMUNICATION*

As outlined in the previous sections, there is much that can be learned about the different types of hazards that might be present in the workplace and on how to avoid them. From an ethical and legal perspective employees have a right to know about these hazards so they can make informed decisions about how to respond to them. Providing safety information to workers can also be thought of from the control perspective as either a way of preventing unsafe acts by alerting, reminding, or instructing people what to do or as a strategy for ensuring safe behavior by building safety awareness and motivating people to behave safely.

### 7.1 Legal Requirements

In most industrialized countries, governmental regulations require that certain forms of safety information be provided to workers. For example, in the United States, the EPA has developed several labeling requirements for toxic chemicals. The DOT makes specific provisions

regarding the labeling of transported hazardous materials. OSHA has promulgated a hazard communication standard that applies to workplaces where toxic or hazardous materials are in use. Training, container labeling, and material data safety sheets are all required elements of the OSHA hazard communication standard.

In the United States, the failure to warn also can be grounds for litigation holding manufacturers and others liable for injuries incurred by workers. In establishing liability, the *theory of negligence* considers whether the failure to adequately warn is unreasonable conduct based on (1) the foreseeability of the danger to the manufacturer, (2) the reasonableness of the assumption that a user would realize the danger, and (3) the degree of care that the manufacturer took to inform the user of the danger. The *theory of strict liability* only requires that the failure to warn caused the injury or loss.

### 7.2 Sources of Safety Information

Manufacturers and employers throughout the world provide a vast amount of safety information to workers. The many sources of safety information now made available to workers include materials provided in training courses, material safety data sheets, written procedures, safety signs, product labels, and instruction manuals.

---

* The material in this section is adapted for the most part from Lehto and Miller (1997).

**Table 13  Objectives and Example Sources of Safety Information Mapped to Accident Sequence**

| | Task Stage in Accident Sequence | | | |
| | Prior to Task | Routine Task Performance | Abnormal Task Conditions | Accident Conditions |
| --- | --- | --- | --- | --- |
| Objectives (behavioral) | Educate and persuade worker of the nature and level of risk, precautions, remedial measures, and emergency procedures | Instruct or remind worker to follow safe procedures or take precautions | Alert worker of abnormal conditions; specify needed actions | Indicate locations of safety and first aid equipment, exits, and emergency procedures; specify remedial and emergency procedures |
| Example sources | Training Manuals, videos, or programs; hazard communication programs; MSDSs; safety propaganda safety feedback | Instruction manuals; job performance aids; checklists; written procedures; warning signs and labels | Warning signals: visual, auditory, or olfactory; temporary tags, signs, barriers, or lock-outs | Safety information signs, labels, and markings; MSDSs |

*Source*: Reprinted with permission from Lehto and Miller (1997).

Information provided by each of these sources varies in its behavioral objectives, intended audience, content, level of detail, format, and mode of presentation. Each source also provides its information at different stages in a way that corresponds to behavioral objectives and when it is provided (Table 13).

Sources of information, such as safety training materials, hazard communication programs, and various forms of safety propaganda, including safety posters and campaigns, are used to educate workers about risks and persuade them to behave safely. Such information is often provided away from the job in the classroom or safety meetings. Occasional safety and health meetings are especially appropriate when things are changing in manufacturing areas that may have safety and health implications. Meetings called to inform operators of some expected changes and to elicit employee suggestions about details of those changes are also very valuable, especially if they affect safety and health.[*] Inexperienced workers are often the target audience, and the information provided is often quite detailed and focused on building safety awareness and motivating people to behave safely.

Other sources of information, such as written procedures, checklists, instructions, warning signs, and product labels, often provide critical safety information to the operator during routine task performance. This information usually consists of brief statements that either instruct less skilled workers or remind skilled workers to take necessary precautions. Following this approach can help prevent workers from omitting precautions or other critical steps in a task. Statements providing such information are often embedded at the appropriate stage within step-by-step instructions describing how to perform a task. Warning signs at appropriate locations can

play a similar role. For example, a warning sign located at the entrance to a workplace might state that hard hats must be worn before entering.

At the next stage in the accident sequence, highly conspicuous and easily perceived sources of safety information alert workers of abnormal or unusually hazardous conditions. Examples include warning signals, safety markings, tags, signs, barriers, or lock-outs. Warning signals can be visual (flashing lights, movements, etc.), auditory (buzzers, horns, tones, etc.), olfactory (odors), tactile (vibrations), or kinesthetic. Certain warning signals are inherent to products when they are in hazardous states (i.e., the odor released upon opening a container of acetone). Others are designed into machinery or work environments. Safety markings refer to methods of nonverbally identifying or highlighting potentially hazardous elements of the environment (i.e., by painting step edges yellow or emergency stops red). Safety tags, barriers, signs, or lock-outs are placed at the point of hazard and are often used to prevent workers from entering areas or activating equipment during maintenance, repair, or other abnormal conditions.

At the final stage in the accident sequence, the focus is on expediting worker performance of emergency procedures at the time an accident is occurring or performance of remedial measures shortly after the accident. Safety information signs and markings conspicuously indicate facts critical to adequate performance of emergency procedures (e.g., the locations of exits, fire extinguishers, first-aid stations, emergency showers, eye wash stations, emergency releases). Product safety labels and material safety data sheets may specify remedial and emergency procedures to be followed.

Before safety information can be effective, at any stage in the accident sequence, it must first be noticed and understood and, if the information is not immediately applicable, also be remembered. Then, the worker must both decide to comply with the provided message and be physically able to do so. Successfully attaining

---

[*] Employee participation greatly helps employee motivation and the building of a team effort.

each of these steps for effectiveness can be difficult. Guidelines describing how to design safety information are of some assistance, as expanded upon below.

### 7.3 Design Guidelines

Standard-setting organizations, regulatory agencies, and the courts through their decisions have traditionally both provided guidelines and imposed requirements regarding when and how safety information is to be provided. More recently, there has been a trend toward developing guidelines based on scientific research concerning the factors which influence the effectiveness of safety information.

### 7.3.1 Voluntary Standards

A large set of existing standards provide voluntary recommendations regarding the use and design of safety information. These standards have been developed by both (1) international groups, such as the United Nations, the European Economic Community (EURONORM), the International Organization for Standardization (ISO), and the International Electrotechnical Commission (IEC), and (2) national groups, such as the American National Standards Institute (ANSI), the British Standards Institute, the Canadian Standards Association, the German Institute for Normalization (DIN), and the Japanese Industrial Standards Committee.

Among consensus standards, those developed by ANSI in the United States are of special significance. Seven ANSI standards focusing on safety signs, labels, and manuals have been developed and revised on a recurring basis: (1) ANSI Z535.1, *Safety Color Code*; (2) ANSI Z535.2, *Environmental and Facility Safety Signs*; (3) ANSI Z535.3, *Criteria for Safety Symbols*; (4) ANSI Z535.4, *Product Safety Signs and Labels*; (5) ANSI Z535.5, *Safety Tags and Barricade Tapes (for Temporary Hazards)*; (6) ANSI Z535.6, *Product Safety Information in Product Manuals, Instructions, and Other Collateral Materials*. Other standards, such as (7) ANSI Z129.1, *Hazardous Industrial Chemicals—Precautionary Labeling*, should be reviewed and applied when required.

### 7.3.2 Design Specifications

Design specifications can be found in the consensus and governmental safety standards discussed above specifying how to design (1) material safety data sheets (MSDSs), (2) instructional labels and manuals, (3) safety symbols, and (4) warning signs, labels, and tags.

***Material Safety Data Sheets*** The OSHA hazard communication standard (29 CFR 1910.1200) specifies that employers must have a MSDS in the workplace for each chemical that is considered a health hazard. Most chemicals used today will have MSDSs provided by the supplier. In addition, many online resources are available for MSDSs, such as Cornell University (http://www.ehs.cornell.edu/msds/msds.cfm).

For in-process or internally used chemicals only, the standard requires that each sheet be written in English, list its date of preparation, and provide the chemical and common name of hazardous chemicals contained. It also requires the MSDS to describe (1) physical and chemical characteristics of the hazardous chemical, (2) physical hazards, including potential for fire, explosion, and reactivity, (3) health hazards, including signs and symptoms of exposure, and health conditions potentially aggravated by the chemical, (4) the primary route of entry, (5) the OSHA permissible exposure limit, the ACGIH threshold limit value, or other recommended limits, (6) carcinogenic properties, (7) generally applicable precautions, (8) generally applicable control measures, (9) emergency and first-aid procedures, and (10) the name, address, and telephone number of a party able to provide, if necessary, additional information on the hazardous chemical and emergency procedures.

Several publications provide assistance in creating MSDSs, such as OSHA form 174 (http://www.osha.gov/dsg/hazcom/msds-osha174/msdsform.html) and ANSI Z400.1: Hazardous Industrial Chemicals—Material Safety Data Sheets—Preparation.

***Instructional Labels and Manuals*** The recent ANSI Z535.6 product safety information in product manuals, instructions, and other collateral materials was published in 2006. This standard focuses on the elements and format that should be considered when developing safety information other than warning labels and signs. This usually takes the form of user manuals and instructions.

***Safety Symbols*** Numerous standards throughout the world contain provisions regarding safety symbols. Among such standards, the ANSI Z535.3 standard, Criteria for Safety Symbols, is particularly relevant for industrial practitioners. The standard presents a significant set of selected symbols shown in previous studies to be well understood by workers in the United States. Perhaps more importantly, the standard also specifies methods for designing and evaluating safety symbols. Important provisions include (1) new symbols must be correctly identified during testing by at least 85% of 50 or more representative subjects, (2) symbols which do not meet the understandability criteria should only be used when equivalent word messages are also provided, and (3) employers and product manufacturers should train users regarding the intended meaning of the symbols. The standard also makes new symbols developed under these guidelines eligible to be considered for inclusion in future revisions of the standard.

***Warning Signs, Labels, and Tags*** ANSI and other standards provide very specific recommendations for how to design warning signs, labels, and tags. These include, among other factors, particular signal words and text, color-coding schemes, typography, symbols, arrangement, and hazard identification (Table 14).

The most commonly used signal words are DANGER, to indicate the highest level of hazard; WARNING, to represent an intermediate hazard; and CAUTION, to indicate the lowest level of hazard. Color-coding methods, also referred to as a "color system," consistently associate colors with particular levels of hazard. For example, red is used in all of the

**Table 14 Summary of Recommendations in Selected Warning Systems**

| System | Signal Words | Color Coding | Typography | Symbols | Arrangement |
|---|---|---|---|---|---|
| ANSI Z129.1 Precautionary Labeling of Hazardous Chemicals | Danger<br>Warning<br>Caution<br>Poison<br>optional words for "delayed" hazards | Not specified | Not specified | Skull-and-crossbones as supplement to words; acceptable symbols for three other hazard types | Label arrangement not specified; examples given |
| ANSI Z535.2 Environmental and Facility Safety Signs | Danger<br>Warning<br>Caution<br>Notice<br>[general safety]<br>[arrows] | Red<br>Orange<br>Yellow<br>Blue<br>Green<br>as above; B&W otherwise<br>per ANSI Z535.1 | Sans serif, uppercase, acceptable typefaces, letter heights | Symbols and pictographs per ANSI Z535.3 | Defines signal word, word message, symbol panels in 1–3 panel designs; four shapes for special use; can use ANSI Z535.4 for uniformity |
| ANSI Z535.4 Product Safety Signs and Labels | Danger<br>Warning<br>Caution | Red<br>Orange<br>Yellow<br>per ANSI Z535.1 | Sans serif, uppercase, suggested typefaces, letter heights | Symbols and pictographs per ANSI Z535.3; also SAE J284 Safety Alert Symbol | Defines signal word, message, pictorial panels in order of general to specific; can use ANSI Z535.2 for uniformity; use ANSI Z129.1 for chemical hazards |
| ANSI Z535.6 Product safety information in product manuals, instructions, and other collateral materials | Danger<br>Warning<br>Caution | Red<br>Orange<br>Yellow<br>per ANSI Z535.1 | Sans serif, uppercase, suggested typefaces, letter heights | Symbols and pictographs per ANSI Z535.3; also SAE J284 Safety Alert Symbol | Defines signal word, message, pictorial panels in order of general to specific; can use ANSI Z535.2 for uniformity |
| OSHA 1910.145 Specification for Accident Prevention Signs and Tags | Danger<br>Warning (tags only)<br>Caution<br>Biological Hazard, BIOHAZARD, or symbol<br>[safety instruction]<br>[slow-moving vehicle] | Red<br>Yellow<br>Yellow<br>Fluorescent Orange/Orange-Red<br>Green<br>Fluorescent Yellow-Orange & Dark Red<br>per ANSI Z535.1 | Readable at 5 ft or as required by task | Biological Hazard Symbol. Major message can be supplied by pictograph (tags only); Slow-Moving Vehicle (SAE J943) | Signal word and major message (tags only) |
| OSHA 1910.1200 [Chemical] Hazard Communication | Per applicable requirements of EPA, FDA, BATF, and CPSC | | In English | | Only as MSDS |

*Source*: Adapted from Lehto and Miller (1986) and Lehto and Clark (1990).

standards in Table 9 to represent the highest level of danger. Explicit recommendations regarding typography are given in nearly all the systems. The most general commonalty between the systems is the recommended use of san serif typefaces. Varied recommendations are given regarding the use of symbols and pictographs.

Certain standards also specify the content and wording of warning signs or labels in some detail. For example, ANSI Z129.1 specifies that chemical warning labels include (1) identification of the chemical product or its hazardous component(s), (2) signal word, (3) statement of hazard(s), (4) precautionary measures, (5) instructions in case of contact or exposure, (6) antidotes, (7) notes to physicians, (8) instructions in case of fire and spill or leak, and (9) instructions for container handling and storage. This standard also specifies a general format for chemical labels that incorporate these items. The standard also provides extensive and specific recommended wordings for particular messages.

### 7.3.3 Cognitive Guidelines

Design specifications, such as those discussed above, can be useful to developers of safety information. However, many products and situations are not directly addressed by standards or regulations. Certain design specifications are also scientifically unproven. In extreme cases, conforming with standards and regulations can reduce the effectiveness of safety information. To ensure effectiveness, developers of safety information consequently may need to go beyond safety standards. To address this issue, the International Ergonomics Association (IEA) and International Foundation for Industrial Ergonomics and Safety Research (IFIESR) supported an effort to develop guidelines for warning signs and labels (Lehto, 1992) which reflect published and unpublished studies on effectiveness and have implications regarding the design of nearly all forms of safety information.

Six of these guidelines, presented in slightly modified form, are as follows: (1) Match sources of safety information to the level of performance at which critical errors occur for the relevant population. (2) Integrate safety information into the task and hazard-related context. (3) Be selective. (4) Make sure that the cost of complying with safety information is within a reasonable level. (5) Make symbols and text as concrete as possible. (6) Simplify the syntax of text and combinations of symbols. Satisfying these guidelines requires consideration of a substantial number of detailed issues as addressed in the earlier parts of this chapter.

## 8  FINAL REMARKS

Much more information is available on each of the topics noted here, and many issues are not addressed. However, the presented material should be enough to familiarize the reader with the importance of safety and health, types of occupational hazards, causes of accidents, control strategies, and important functions of occupational safety and health management. There are numerous books on the subject of occupational safety and health management and engineering as well as specialty books on subjects such as toxicology, human error, system engineering, reliability, and human factors engineering. The Web is another important source of information. Most safety organizations, such as the NSC, Board of Certified Safety Professionals, OSHA, NIOSH, and BLS, have websites offering large amounts of helpful information. Contact information for many of these sources of additional information is provided below.

# CHAPTER 26

# HUMAN ERROR AND HUMAN RELIABILITY ANALYSIS

**Joseph Sharit**
**University of Miami**
**Coral Gables, Florida**

## 1 INTRODUCTION

### 1.1 Some Perspectives on Human Error

A fundamental objective of human factors and ergonomics is to design and facilitate the control of various artifacts, such as devices, systems, interfaces, rules, and procedures, to enable safe and effective performance outcomes. In principle, the realization of this goal entails a detailed understanding of how these artifacts might bear upon the limitations and capabilities of their users. It is when the consequences related to the artifact's use are judged to be sufficiently harmful or inappropriate that people may be conferred with the attribution of human error. These people might include those responsible for conceptualizing and designing the artifact; those responsible for installing, maintaining, or providing instruction on its use; those who determine and oversee the rules governing its use; or those who actually use it.

Concerns for human error were a major influence in establishing the area of human factors (Helander, 1997)

and have since become increasingly emphasized in product and system design and in the operations of various organizations. Human error is also often on the minds of the general public as they acknowledge, if not fully understand, the failures in their everyday interactions with products or in their situational assessments or are swept up into the media's coverage of high-profile accidents that are often attributed to faulty human actions or decisions. Yet, despite the apparent ubiquity of human error, its attribution has been far from straightforward.

For example, for a good part of the twentieth century the dominant perspective on human error by many U.S. industries was to attribute adverse outcomes to the persons whose actions were most closely associated to these events—that is, to the people who were working at what is now often referred to as the "sharp end." Likewise, most aircraft crashes were historically blamed on pilot error and, as in the industrial sector, there was little inclination to scrutinize the design of the tools or system

or the situations with which the human was expected to coexist.

In contrast, in the more current perspective the human is deemed to be a reasonable entity at the mercy of an array of design, organizational, and situational factors which can lead to behaviors external observers come to regard, although to some often unfairly, as human errors. The appeal of this view should be readily apparent in each of the following two cases. The first case involves a worker who is subjected to performing a task in a restricted space. While attempting to reach for a tool, the worker's forearm inadvertently brushes against a switch whose activation results in the emission of heat from a device. Visual feedback concerning the activation is not possible, due to the awkward posture the worker must assume; tactile cues are not detectable due to requirements for wearing protective clothing; and auditory feedback from the switch's activation, which is normally barely audible, is not perceived due to ambient noise levels. Residual vapors originating from a rarely performed procedure during the previous shift ignite, resulting in an explosion.

In the second case, a worker adapts the relatively rigid and unrealistic procedural requirements dictated in a written work procedure to demands that continually materialize in the form of shifting objectives, constraints on resources, and changes in production schedules. Management tacitly condones these procedural adaptations, in effect relying on the resourcefulness of the worker for ensuring that its goals are met. However, when an unanticipated scenario causes the worker's adaptations to result in an accident, management is swift to renounce any support of the worker's actions that were in violation of work procedures.

In the first case the worker's action that led to the accident was unintentional; in the second case the worker's actions were intentional. In both cases, however, whether the person committed an *error* is debatable. One view that is consistent with this position would shift the blame for the adverse consequences from the *actor* to management or the designers. *Latent management* or *latent designer errors* (Reason, 1997)—that is, actions and decisions that occurred at the "blunt end"—would thus absolve the actor from human error in each of these cases. The worker, after all, was in the heat of the battle, performing "normal work," responding to the work context in reasonable, even skillful ways. The human does not want his or her actions or decisions to result in a negative consequence; in fact, such a desire would constitute sabotage, which is not within the realm of the topic of human error. In a sense, the human was "set up to fail" due to the context or situation in which they were operating (Spurgin, 2010).

Of course, the process of shifting blame does not have to end with designers. In the current landscape of global competition designers may face pressures that limit their ability to adequately investigate the conditions under which their products will be used or to become sufficiently informed about the knowledge and resources users would have available to them when using these products. Management, or the organizations they represent and lead, would then seem to be the true architects of human failure, but even this attribution of blame may be misleading. Regulatory agencies or even the federal government may have laid the groundwork, by virtue of poor assessments of needed control mechanisms and through misdirected priorities, for the faulty policies and decisions on the part of organizations and ultimately for shaping or at least impacting the entrepreneurial and managerial cultures of these organizations (Section 6). Governments themselves, however, could hardly be expected to provide certainty in solutions and policies as they struggle to make sense of the information streaming from the complex and fluid milieu of social, political, and economic forces.

Nonetheless, societal and organizational prescriptions in the form of policies and other types of remedies are powerful forces. Workers who disagree with these policies, such as the worker in the case above who adapted a procedure in the face of existing evidence, are thus risking being blamed for negative outcomes, especially when such forces that run through an organization are "hidden and undisclosed" (Dervin, 1998). At any rate, what should be fairly clear is that attempts at pinpointing the latent sources of human error or resolving how latent sources can collectively contribute to human error can be far from straightforward.

Another basis for dismissing attributions of human error derives from the doubt capable of being cast on the error attribution process itself (Dekker, 2005). By virtue of having knowledge of events, especially bad events such as accidents, outside observers are able (and perhaps even motivated) to invoke a backward series of rationalizations and logical connections that has neatly filtered out the subtle and complex situational details that are likely to be the basis for the perpetrating actions. Whether this process of establishing causality is due to convenience, *hindsight bias* (Fischhoff, 1975; Christoffersen and Woods, 1999; Dekker, 2001), or the inability to determine or comprehend the perceptions and assessments made by the actor that interlace the more prominently observable events, the end result is a considerable underestimation of the influence of the context within which the person acts. Ultimately, this obstruction at establishing cause and effect jeopardizes the ability to learn from accidents and consequently the ability to predict or prevent future failures.

Even the workers themselves, if given the opportunity in each of these cases to examine or reflect upon their performance, may acknowledge their actions as errors, easily spotting all the poor decisions and improperly executed actions, when in reality, within the frames of references at the time the behaviors occurred, their actions were in fact reasonable and constituted "mostly normal work." The challenge, according to Dekker (2005), is "to understand how assessments and actions that from the outside look like errors become neutralized or normalized so that from the inside they appear unremarkable, routine, normal" (p. 75).

This view is also very consistent with that of Hollnagel (2004), who considers both normal human performance and performance failures (outcomes of actions that differ from what was intended or required) as *emergent properties* of mutual dependencies that are

induced by the complexity and demands arising from the entire system. Therefore, it is not so much the variability of human actions that is responsible for failures but the variability in the context and conditions to which the human is trying to adjust. This variability can result in irregular and unpredictable inputs (e.g., other people in the system acting in unexpected ways); incompatibility between demands (e.g., conflicting or unreasonable production requests) and available resources (e.g., lack of time, lack of training or experience for handling the situation, or limits in cognitive capacity); and working conditions falling outside of normal limits (e.g., noise, poor communication channels, or inappropriate work schedules). Furthermore, system outputs that fail to comply with expectations can result in protracted irregularity in inputs, leading to cycles of variability to which the human must adjust.

While it is fair to assume that normally humans do not want to commit errors, there are situations where human error is not only acceptable but also desirable. Mistakes during training exercises are often essential for developing the deductive, analogical, and inferential skills needed to acquire expertise for handling routine problems as well as the adaptability and creativity required for coping with less foreseen situations and, more generally, for learning.

In fact, it is natural for humans, when faced with uncertainty, to resort to exploratory trial-and-error behavior in order to replace false beliefs and assumptions with valid frames of reference for assessing and solving problems and situations. In these learning situations, the benefits of making errors are expected to outweigh the costs. During the early stages of the U.S. space rocket program there is anecdotal evidence that scientists actually desired failures during testing phases, in much the same way that designers of complex software sometimes do, as these failures provide insights into improvements, and ultimately more effective and robust designs, that would otherwise not have been apparent.

## 1.2 Defining Human Error

The position taken here is that human error is a real phenomenon, if only for the simple fact that humans are fallible. When this fallibility, in the form of committed or omitted human actions, appears in retrospect to be linked to undesirable consequences, an attribution of human error is often made. It can be argued that the choice of the term *human error* is unfortunate as in many circumstances (some may even claim in all circumstances barring malicious behavior) the stigma that is bestowed by virtue of using this term is inappropriate and misleading.

Human error, especially in the form of unintended or mistaken actions, is very much a two-sided coin, as it has at its roots many of the same processes of attention and architectural features of memory that also enable humans to adapt, abstract, infer, and create. It is certainly not incorrect, though perhaps a bit too convenient, to explain unintended *action slips* (Section 3.1), such as the activation of an incorrect control or the selection of the wrong medication, as rational responses in contexts characterized by pressures, conflicts, ambiguities, and

fatigue. In reality, it is human fallibility, in all its guises, that infiltrates these contexts. It is the task of human factors researchers and practitioners to examine and understand this interplay between fallibility and context as humans carry out their various activities. This knowledge could then be used to predict the increased possibility for certain types of errors, ultimately enabling safer and more productive designs.

It is not easy arriving at a satisfying definition of human error. Hollnagel (1993) preferred the term *erroneous action* to human error, which he defined as "an action which fails to produce the expected result and which therefore leads to an unwanted consequence" (p. 67). This definition as well as Sheridan's (2008) definition of human error as an action that fails to meet some arbitrary implicit or explicit criterion both allude to the subjective element that definitions of human error must incorporate.

Another term often used by Hollnagel, and which is frequently used throughout this chapter, is *performance failure*. While this term also implies some form of negative outcome related to human actions, it does so with the recognition that this outcome derives mostly from the intersection of "normal" human performance variability with "normal" system variability. The implication is that a different point of intersection may have very well brought about a favorable result.

Dekker's (2005) view of errors as "*ex post facto* constructs rather than as objective, observed facts" (p. 67) is based on the accumulated evidence for the predisposition of hindsight bias (Section 1.1). Specifically, observers (including the people who may have been recent participants of the unwanted events being investigated) impose their knowledge in the form of assumptions, facts, past experiences, and future intentions to transform what was in fact inaccessible information at the time into neatly unfolding sequences of events and deterministic schemes that are capable of explaining any adverse consequence. These observer and hindsight biases presumably do not bring us any closer to understanding the experiences of the actor in the actual situation for whom there is no error—"the error only exists by virtue of the observer and his or her position on the outside of the stream of experience" (p. 66).

What seems to be indisputable, at least in current thinking, is that human error involves some form of *attribution* that is based on the circumstances surrounding the offending behavior and the expectations held by some entity concerning the corresponding actor. The entity—a supervisor, designer, work team, regulatory agency, organization, the public, or even the person whose performance was directly linked to the adverse event—decides, based on the circumstances, whether an attribution of human error is called for.

The process of attribution of error obviously will be subject to a variety of influences. These would include cultural norms that dictate, for example, the standards to which designers, managers, and operators are held to by their organizations and to which regulatory agencies and the public hold organizations. Thus, a highly experienced pilot or nuclear power plant maintenance worker would probably not be expected to omit an important

step in a check-off procedure, even if distraction at an inopportune time and poor design of the procedure were obvious culprits. But there would be less expectation that a second-year medical resident in a trauma center, thrust into a leadership role in the absence of more senior personnel, would not make an error related to the management of multiple patients with traumatic injuries. There may, however, be an attribution of error by a state regulatory agency directed at the health care organization's management stemming from the absence or poor oversight of protocols intended for preventing these highly vulnerable allocations of responsibility.

The attribution of human error thus also encompasses actions or decisions whose unwanted outcomes may occur at much later points in time or following the interjection of many other actions by other people. Even in cases where such "blunter" actions have not resulted in adverse outcomes, an entity may consider such decisions to be in error based on its belief that unwanted consequences had been fortuitously averted.

Although intentional violations of procedures are a great concern in many industries, these acts are typically excluded from attributions of human error when the actions have gone as planned. For example, violations in rigid "ultrasafe and ultraregulated systems" are often required for effectively managing work constraints (Amalberti, 2001). However, when violations result in unforeseen and potentially hazardous conditions, managers responsible for the design of and compliance with the violated procedures may attribute human error to these actions (Section 1.1).

The attribution of human error becomes more blurred when humans knowingly implement strategies in performance that will result in some degree of unwanted consequences. For example, a worker may believe an action in a particular circumstance would avert the possibility of more harmful consequences. Even if these strategies come off as intended, depending on the boundaries of acceptable outcomes established or perceived by external observers such as managers or the public, the human's actions may in fact be considered to be in error.

Accordingly, a person's ability to provide a reasonable argument for behaviors that resulted in unwanted consequences does not necessarily exonerate the person from the *attribution* of error. What of actions the person intends to commit that are normally associated with acceptable outcomes but that, due to an unusual collection of circumstances, result in adverse outcomes? These would generally not be attributed to human error except perhaps by unforgiving stakeholders who are compelled to exact blame.

## 2 UNDERSTANDING HUMAN ERROR

### 2.1 Basic Framework: Human Fallibility, Context, and Barriers

Figure 1 presents a very basic framework for understanding human error that consists of three components. The *human fallibility* component addresses fundamental sensory, cognitive, and motor limitations of humans as well as a host of other *behavioral tendencies* that predispose humans to error. The *context* component refers to situational variables that can shape, influence, force, or otherwise affect the ways in which human fallibility, in the form of normal human performance variability, can play a role in bringing about adverse consequences. This variability encompasses not only the variability that derives from fundamental sensory, cognitive, and motor considerations but also the more "deliberate and purposeful" variability that, within the context of complex system operations, gives rise to the adaptive adjustments people make (Hollnagel, 2004). Finally, the *barriers* component concerns the various ways in which human errors or performance failures can be contained.

A number of points concerning this framework should be noted. First, human error is viewed as arising primarily from some form of *interplay* between human fallibility and context. This is probably the most intuitive way for practitioners to understand how human errors come about. Interventions that minimize human dispositions to fallibility, for example, by placing fewer memory demands on the human, are helpful, but only to the extent that they do not create new contexts that,

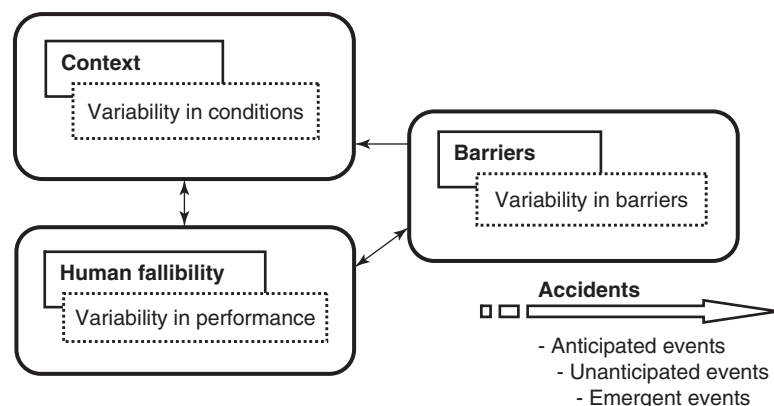

**Figure 1** Framework for understanding human error and its potential for adverse consequences.

in turn, can create new ways in which human performance variability can translate into negative outcomes. Similarly, interventions intended to reduce the error-producing potential of work contexts, for instance, by introducing new protocols for communication, could unsuspectingly produce new ways in which human fallibility can be brought to bear.

Second, many of the elements that comprise human fallibility can potentially overlap, as can many of the elements that encompass context, reflecting the interactive complexity that can be manifest among these factors. Third, because of the variability that exists in both the fallibility elements and the contextual elements, the product of their interplay will also necessarily be dynamic in nature. One consequence of this interplay is the need for anticipation, which produces human performance that is *proactive*, in addition to being *reactive*, making possible the human's ongoing adaptive responses. These responses, in turn, can alter the context that, at the same time, is experiencing its own exogenously driven variability.

From this superimposition of human performance variability on situational variability, accidents can *emerge* (Figure 1). This does not exclude the possibility for predictions of accidents based on underlying *linear* (and to some extent interactive) mechanisms, but it does dramatically alter the conceptualization of the accident process and the implications for its management.

Fourth, barriers intended to prevent the propagation of errors to adverse outcomes such as accidents could also affect the context, as well as human perceptions of the work context, and thus ultimately human performance. These interactions are often ignored or misunderstood in evaluating a system's risk potential.

In some accident models, the possibility for progressing from human error to an adverse outcome depends on how the "gaps" (the windows of opportunity for penetration) in existing barriers are aligned (Reason, 1990). Generally, the likelihood that errors will traverse these juxtaposed barriers is low, which is the reason for the much larger number of near misses that are observed compared to events with serious consequences. The avoidance or containment of or rapid recovery from accidents, including those resulting from *emerging phenomena*, may very well characterize the *resilience* of an organization (Section 6).

Finally, this framework (Figure 1) is intended to encompass various perspectives on human error that have been proposed, in particular, the human factors, cognitive engineering, and sociotechnical perspectives [Center for Chemical Process Safety (CCPS), 1994]. In the human factors perspective, error is the result of a mismatch between task demands and human mental and physical capabilities. Presumably, this perspective allows only general predictions of human error to be made. For example, cluttered displays or interfaces that impose heavy demands on working memory are likely to overload perceptual and memory processes (Section 2.2.1), possibly leading to the omission of actions or the confusion of one control with another. Guidelines that have been proposed for designing displays (Wickens et al., 2004) are offered as a means

for diminishing mismatches between demands and capabilities and thus the potential for error.

The cognitive engineering perspective, in contrast, emphasizes detailed analysis of work contexts (Section 3) coupled with analysis of the human's intentions and goals. Although both the human factors and cognitive engineering perspectives on human error are very concerned with human information processing, cognitive engineering approaches attempt to derive more detailed information about how humans acquire and represent information and how they use it to guide actions. This emphasis provides a stronger basis for linking underlying cognitive processes with the external form of the error and thus should lead to more effective classifications of human performance and human errors. As a simple illustration of the cognitive engineering perspective, Table 1 demonstrates how the same external expression of an error could derive from various underlying causes.

Sociotechnical perspectives on human error focus on the potential impact of management policies and organizational culture on shaping the contexts within which people act. These "higher order" contextual factors are capable of exacting considerable influence on the designs of workplaces, operating procedures, training programs, job aids, and communication protocols and can produce excessive workload demands by imposing multiple conflicting and shifting performance objectives and by exerting pressure to meet production goals, often at the expense of safety considerations (Section 6).

## 2.2  Human Fallibility

### 2.2.1  Human Information Processing

A fundamental basis for many human errors derives from underlying limitations and tendencies that characterize human sensory, cognitive, and motor processes (Chapters 3–5). These limitations are best understood by considering a generic model of human information processing that conceptualizes the existence of various *processing resources* for handling the flow and transformation of information (Figure 2).

According to this model, sensory information received by the body's various receptor cells gets stored in a system of sensory registers that has an enormous storage capacity. Through the process of *selective attention*, subsets of this vast collection of briefly available information become designated for further processing in an early stage of information processing known as *perception*. Here, information can become meaningful through comparison with information in *long-term memory* (LTM). This could promptly trigger some form of response or require the need for further processing in a short-term memory store referred to as *working memory* (WM).

A good deal of our conscious effort is dedicated to WM activities such as visualizing, planning, evaluating, conceptualizing, and making decisions, and much of this WM activity depends on information that can be accessed from LTM. The rehearsal of information in WM enables it to be encoded into LTM; otherwise, it decays rapidly. In addition to this time constraint, WM

**Table 1  Examples of Different Underlying Causes of Same External Error Mode**

*Situation:* A worker in a chemical processing plant closes valve B instead of nearby valve A, which is the required action as set out in the procedures. Although there are many possible causes of this error, consider the following five possible explanations.

1. The valves were close together and badly labeled. The worker was not familiar with the valves and therefore chose the wrong one.

   *Possible cause:* wrong identification compounded by lack of familiarity leading to wrong intention (once the wrong identification occurred, the worker intended to close the wrong valve).

2. The worker may have misheard instructions issued by the supervisor and thought that valve B was the required valve.

   *Possible cause:* communications failure giving rise to a mistaken intention.

3. Because of the close proximity of the valves, even though he intended to close valve A, he inadvertently operated valve B when he reached for the valves.

   *Possible cause:* correct intention but wrong execution of action.

4. The worker closed valve B very frequently as part of his everyday job. The operation of A was embedded within a long sequence of other operations that were similar to those normally associated with valve B. The worker knew that he had to close A in this case, but he was distracted by a colleague and reverted back to the strong habit of operating B.

   *Possible cause:* intrusion of a strong habit due to external distraction (correct intention but wrong execution).

5. The worker believed that valve A had to be closed. However, it was believed by the workforce that despite the operating instructions, closing B had an effect similar to closing A and in fact produced less disruption to downstream production.

   *Possible cause:* violation as a result of mistaken information and an informal company culture to concentrate on production rather than safety goals (wrong intention).

*Source*: Adapted from CCPS (1994). Copyright 1994 by the American Institute of Chemical Engineers. Reproduced by permission of AIChE.

also has relatively severe capacity constraints governing the amount of information that can be kept active. The current contention is that within WM there are separate limited-capacity storage systems for accommodating visual information presented in an analog spatial form and verbal information presented in an acoustical form as well as an attentional control system for coordinating these two storage systems. Ultimately, the results of WM–LTM analysis can lead to a response (e.g., a motor action or decision) or to the revision of one's thoughts.

This overall sequence of information processing, though depicted in Figure 2 as flowing from left to right,

in fact can assume other pathways. For example, it could be manifest in the form of an attention-WM-LTM loop if one was contemplating how to modify a work operation.

With the exception of the system of sensory registers and LTM, the processing resources in this model may require *attention*. Often thought of as *mental effort*, attention is conceptualized here as a finite and flexible endogenous energy source under conscious control whose intensity can be modulated over time. Although the human has the capability for distributing attention among the various information-processing resources, fundamental limitations in attention constrain the capacities of these resources, implying that there is only so much information that can, for example, undergo perceptual coding or WM analysis. Focusing attention on one of these resources will usually handicap, to some degree, the information-processing capabilities of the other resources.

In many situations, attention may be *focused* almost exclusively on WM, for example, during intense problem solving or when conceiving or evaluating plans. Other situations may require the need for dividing attention, which is the basis for *time sharing*. This ability is often observed in people who have learned to rapidly shift attention between tasks. Time-sharing skill may depend on having an understanding of the temporal and knowledge demands of the tasks and the possibility that one (or more) of the tasks has become automated in the sense that very little attention is needed for its performance. Various dichotomies within the information-processing system have been proposed, for example, between the visual and auditory modalities and between early (perceptual) versus later (central and response) processing (Figure 2), to account for how people are able, in time-sharing situations, to more effectively utilize their processing capacities (Wickens, 1984).

Many design considerations arise from the errors that human sensory and motor limitations can cause or contribute to. Indeed, human factors studies are often preoccupied with deriving design guidelines for minimizing such errors. Knowledge concerning human limitations in contrast sensitivity, hearing, bandwidth in motor movement, and sensing tactile feedback can be used to design visual displays, auditory alarms, manual control systems, and protective clothing (such as gloves that are worn in surgery) that are less likely to produce errors in detection and response.

Much of the focus on human error, however, is on the role that cognitive processing plays. Even seemingly simple situations involving errors in visual processing may in fact be rooted in much more complex information processing. For example, consider the following prescription medication error, which actually occurred. A physician opted to change the order for 50 mg of a leukemia drug to 25 mg by putting a line through the zero in the "50" and inserting a "2" in front of the "5." The resulting dose was perceived by the pharmacist as 250 mg and led to the death of a 14-year-old boy.

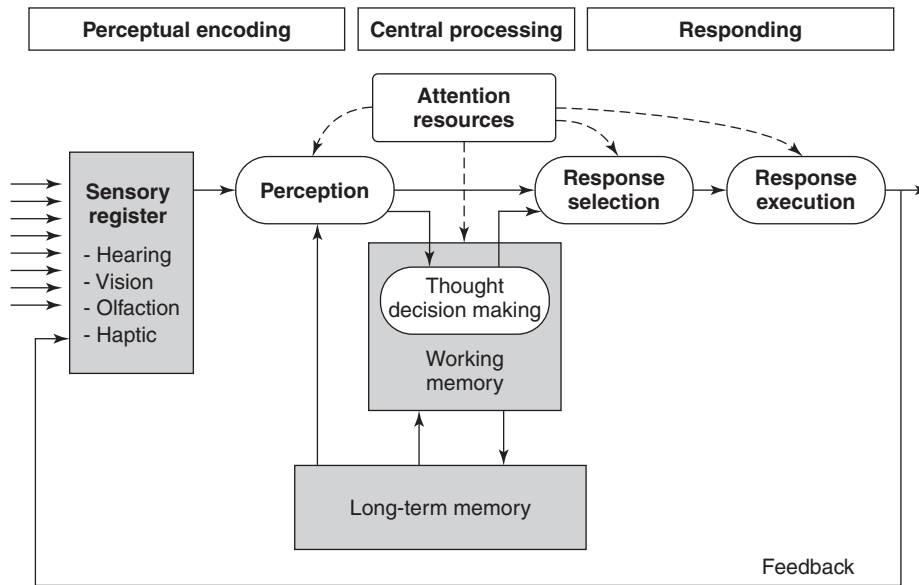
On the surface, this error can be viewed as resulting from normal human variability associated with visual processing—that is, at any given moment, the attention


**Figure 2**   Generic model of human information processing. (Adapted from Wickens et al., 2004. Reproduced by permission of Pearson Education, Inc.)

being directed to a given stimulus is varying and at that critical moment the line through the zero was missed. However, a closer examination of the context may suggest ways in which this normal variability can be influenced, beginning with the fact that the line that was meant to indicate a cross-out was not centered but (due to normal psychomotor variability) was much closer to the right side of the circle. The cross-out at that given moment could then have easily been construed as just a badly written zero. Also, when one considers that perception relies on both *bottom-up* processing (where the stimulus pattern is decomposed into features) and *top-down* processing (where context and the expectations that are drawn from the context are used for recognition of the stimulus pattern), the possibility that a digit was crossed out may have countered expectations (i.e., it does not usually occur).

If one were to further presume that the pharmacist had a high workload (and thus diminished cognitive resources for processing the prescription) and a relative lack of experience or knowledge concerning dosage ranges for this drug, it is easy to understand how this error can come about. The progression from faulty visual processing or misinterpretation of the stimulus to adverse consequences can be put into a more complete perspective when potential barriers are considered, such as an automatic checking system that could have screened the order for a potentially harmful dosage or interactions with other drugs or a procedure that would have required the physician to rewrite any order that had been altered. However, even if these safeguards were in place, which was not the case, it is still possible that they could have been bypassed (Section 2.4).

### 2.2.2   Long-Term Memory's Role in Human Error

Long-term memory has been described as a parallel distributed architecture that is continuously being reconfigured within the brain through selective activation and inhibition of massively interconnected neuronal units (Rumelhart and McClelland, 1986). In the process of adapting to new stimuli or thoughts, the complex interactions that are produced between these neuronal units give rise to the generalizations and rules and ultimately to the knowledge that is so critical to human performance. When we consider the forms in which this knowledge is stored in LTM, we usually distinguish between the general knowledge we have about the world, referred to as *semantic memory*, and knowledge about events, referred to as *episodic memory*.

Items of information, such as visual images, sounds, and thoughts that are processed in WM at the same time and to a sufficient degree, usually become associated with each other in LTM. The ability to retrieve this information from LTM, however, will depend on the strengths of the individual items as well as the strengths of their associations with other items. Increased *frequency* and *recency* of activation are assumed to promote stronger (i.e., more stable) memory traces, which are otherwise subject to negative exponential decays.

Much of our basic knowledge about things can be thought of as being stored in the form of *semantic networks*, which are implemented within LTM through parallel distributed architectures. Other knowledge representation schemes commonly invoked in the human factors literature are *schemas* and *mental models*. Schemas typically represent knowledge organized about

a concept or topic. When they reflect processes or systems for which there are relationships between inputs and outputs that the human can mentally visualize and "experiment with" (i.e., "run," like a simulation program), the schemas are often referred to as *mental models* (Wickens et al., 2004). The organization of knowledge in LTM as schemas or mental models is also likely based on semantic networks.

The constraints associated with LTM architecture can provide many insights into human fallibility and how this fallibility can interact with situational contexts to produce errors. For example, many of the contexts within which humans operate produce what Reason (1990) has termed *cognitive underspecification*, which implies that at some point in the processing of information the specification of information may be incomplete. It may be incomplete due to perceptual processing constraints, WM constraints, LTM (i.e., knowledge) limitations, or external constraints, as when there is little information available on the medical history of a patient undergoing emergency treatment or when piping and instrumentation diagrams have not been updated.

Because the parallel associative networks in our brain have the ability to recall both items of information and patterns (i.e., associations) of information based on *partial matching* of this incomplete input information with the contents of memory, the limitations associated with cognitively underspecified information can be overcome, but at a risk. Specifically, LTM can retrieve items of information that provide a match to the inputs, and these retrieved items of information may enable, by virtue of LTM's associative structure, an entire

rule or idea to become activated. Even if this rule is not appropriate for the particular situation, if the pattern characterizing this rule in LTM is sufficiently *similar* to the input pattern of information, it may still get triggered, possibly resulting in a *mistaken action* (Section 2.2.5).

## 2.2.3 Information Processing and Decision-Making Errors

Human decision making, particularly the kind that takes place in complex dynamic environments without the luxury of extended time and other resources needed for accommodating *normative prescriptive models* (Chapter 7), is an activity fraught with fallibility. As illustrated in Figure 3, this fallibility can arise from a number of information-processing considerations (Figure 2). For example, if the information the human opts to select for examination in WM is fuzzy or incomplete, whether it be facts, rules, or schemas residing in LTM, or information available from external sources such as equipment monitors, computer databases, or other people, intensive interpretation or integration of this information in WM may be needed. Unfortunately, WM is relatively fragile as it is subject to both time and capacity constraints (Section 2.2.2).

Decision-making situations that involve the consideration of different hypotheses as a basis for performing some action also can place heavy demands on WM. Initially, these demands derive from the process of *generating* hypotheses, which is highly dependent on information that can be retrieved from LTM. The *evaluation* of hypotheses in WM may then entail searching

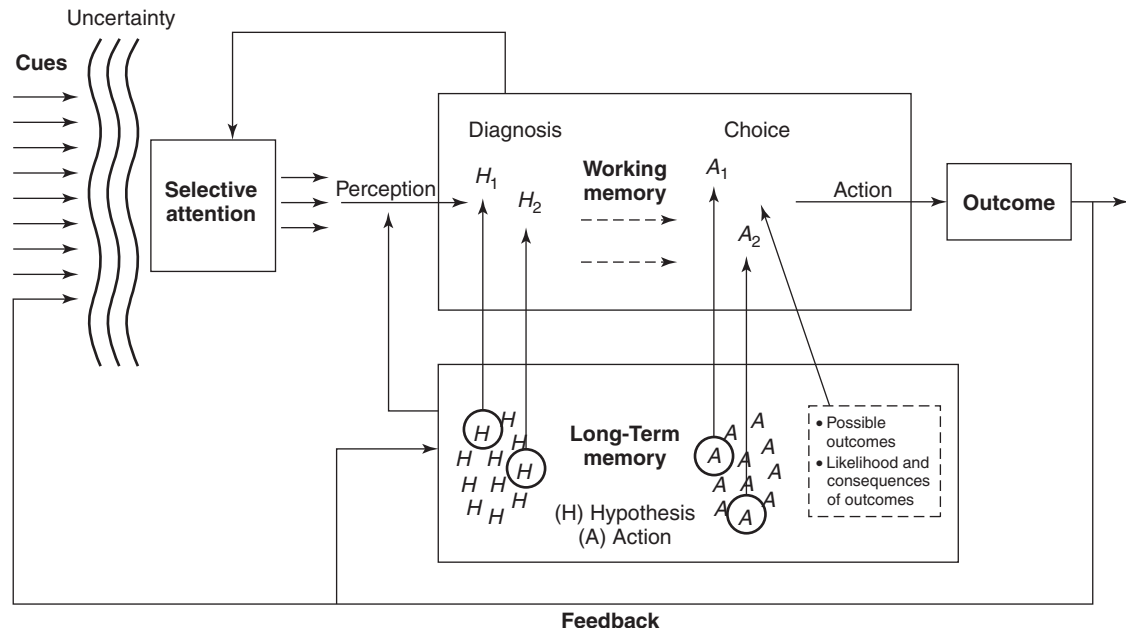

**Figure 3** Information-processing model of decision making. (Adapted from Wickens et al., 2004. Reproduced by permission of Pearson Education, Inc.)

for additional information, which would further increase the load on WM. Although any hypothesis for which adequate support is found can become the basis for an action, there may be a number of possible actions associated with this hypothesis, and they also would need to be retrieved from LTM in order to be evaluated in WM. Finally, the possible outcomes associated with each action, the estimates of the likelihoods of these outcomes, and the negative and positive implications of these outcomes would also require retrieval from LTM for evaluation in WM (Figure 3).

From an information-processing perspective, there are numerous factors that could constrain this decision-making process, particularly those that could influence the amount or quality of information brought into WM and the retrieval of information from LTM. These constraints often lead to shortcuts in decision making, such as *satisficing* (Simon, 1966), whereby people adopt strategies for sampling information that they perceive to be most relevant and opt for choices that appear to them to be good enough for their purposes.

In general, the human's natural tendency to minimize cognitive effort (Section 2.2.5) opens the door to a wide variety of shortcuts or heuristics (Tversky and Kahneman, 1974). These tendencies are usually effective in negotiating environmental complexity but under the right coincidence of circumstances can bias the human toward ineffective choices or actions that can become designated as errors. For example, with respect to the cues of information that we perceive, there is a tendency to overweight cues occurring earlier rather than later in time or that change over time. Often, the information that is acquired early on can influence the shaping of an initial hypothesis; this could, in turn, influence the interpretation of the information that is subsequently acquired. In trying to make sense of this information, WM will only allow for a limited number of possible hypotheses, actions, or outcomes of actions to be evaluated at any time. Moreover, LTM architecture will accommodate these limitations by making information that has been considered more frequently or recently more readily available (the *availability heuristic*) and by enabling its partial-matching capabilities to classify cues as more representative of a hypothesis than may be warranted.

There are many other heuristics (Wickens et al., 2004) that are capable of becoming invoked by virtue of the human's fundamental tendency to conserve cognitive effort. These include *confirmation bias* (the tendency to consider confirming and not disconfirming evidence when evaluating hypotheses); *cognitive fixation* (remaining fixated on initial hypotheses and underutilizing subsequent information); and the tendency to judge an "event" as likely if its features are *representative* of that event (e.g., judging a person as having a particular occupation based on the person's appearance or political ideology, even though the likelihood of having that occupation is extremely low).

Similarly, the human is often found to be biased in matters related to making statistical or probabilistic assessments. One important type of statistical assessment is the ability to recognize the existence of *covariation* between events. This ability can prove essential in ensuring desired outcomes (and avoiding adverse ones), as it provides humans with the capability to control the present and predict the future by virtue of explaining past events (Alloy and Tabachnik, 1984). While debates continue regarding human capabilities at such assessments, there is ample evidence that, when estimating the degree to which two events are correlated, people overemphasize instances in which the events co-occurred and disregard cases in which one event occurred but not the other, leading to overestimation of the relationship between the two events (Peterson and Beach, 1967). Top-down expectancies or preconceptions by people can alter the detection of covariation by making it unlikely that it will be detected if the variables are not expected to be related. Conversely, when relationships between variables are expected, their covariation can be given undue weight at the expense of overlooking or discounting disconfirming evidence, especially when people believe there to be a cause–effect relationship between the variables. In fact, this tendency by people can be viewed as one of the many manifestations of the confirmation bias (Nickerson, 1998).

People also typically overestimate the probability of the joint occurrence of independent events (relative to the objective or estimated probabilities of the individual events) and underestimate the probability that at least one of them will occur (Peterson and Beach, 1967; Tversky and Kahneman, 1974). These tendencies have a number of practical implications, especially when estimation of the probability of success depends on the conjunction of two or more events. For example, in the execution of sequential stepwise procedures, it can lead to overestimation of the probability that the *entire* operation will be performed successfully or completed by a specified time and to underestimation that *some* problem will be encountered in executing the procedure (Nickerson, 2004).

While the human's lack of knowledge of certain concepts and principles that are fundamental to probability theory may explain a few of the findings in this area, limitations in information-processing capacities coupled with overreliance on heuristics that work well in many but not all contexts is probably at the root of many of these human tendencies. Generally, however, one should be cautious when providing explanations of human judgments and behaviors on the basis of cognitive biases. To exclude the possibility that a human's situational assessments are in fact rational, a sound understanding of the specific context is required (Fraser et al., 1992).

## 2.2.4 Levels of Human Performance and Dispositions for Errors

Rasmussen (1986) has described fundamentally different approaches that humans take to processing information based on distinctions between skill-based, rule-based, and knowledge-based (SRK) levels of performance. The distinctions that underlie this *SRK framework* have been found to be particularly appealing for analyzing and predicting different types of human errors.

Activities performed at the *skill-based level* are highly practiced routines that require little conscious

attention. Following an intention for action, which could originate in WM or from environmental cues, the responses associated with the intended activity are so well integrated with the activity's sensory features that they are elicited in the form of highly automatic routines that are "hardwired" to the human's motor response system, bypassing WM (Figure 2).

At the *rule-based level* of performance, use is made of rules that have been established in LTM based on past experiences. WM is now a factor, as rules (of the if–then type) or schemas may be brought into play following the assessment of a situation or problem. More attention by the human is thus required at this level of performance, and the partial matching characteristics of LTM can prove critical.

When stored rules are not effective, as is often the case when new or challenging problems arise, the human is usually forced to devise plans that involve exploring and testing hypotheses and must continuously refine the results of these efforts into a mental model or representation that can provide a satisfactory solution. At this *knowledge-based level* of performance heavy demands on information-processing resources are exacted, especially on WM, and performance is vulnerable to LTM's architectural constraints to the extent that WM is dependent on LTM for problem solving.

In reality, many of the meaningful tasks that people perform represent mixtures of SRK levels of performance. Although performance at the skill-based level results in a significant economy in cognitive effort, the reduction in resources of attention comes at a risk. For example, consider an alternative task that contains features similar to those of an intended task. If the alternative activity is frequently performed and therefore associated with skill-based automatic response patterns, all that is needed is a context that can distract the human from the intention and allow the human to be "captured" by the alternative (incorrect) task. This situation represents example 4 in Table 1 in the case of an inadvertent closure of a valve.

In other situations, the *capture* by a skill-based routine may result in the exclusion of an activity. For example, suppose that task A is performed infrequently and task B is performed routinely at the skill-based level. If the initial steps are identical for both tasks but task A requires an additional step, this step is likely to be omitted during execution of this task. Untimely interruptions are often the basis for such omissions at the skill-based level of performance. In some circumstances, interruptions or moments of inactivity during skill-based routines may instigate thinking about where one is in the sequence of steps. By directing attention to routines that are not designed to be examined, steps could be performed out of sequence (reversal errors) or be repeated (Reason, 1990).

Many of the errors that occur at the rule-based level involve inappropriate matching of either external cues or internally generated information with the conditional components of rules stored in LTM. Conditional components of rules that have been satisfied on a frequent basis or that appear to closely match prevailing conditions are more likely to be activated. Generally, the

prediction of errors at this level of performance would require knowing what rules the human might consider. This, in turn, would require having detailed knowledge not only about the task but also about the process (e.g., training or experience) by which the person acquired rule-based knowledge.

When applying rules, a mistake that can easily occur is the *misapplication of a rule* with proven success (Reason, 1990). This type of mistake often occurs when *first exceptions* are encountered. Consider the case of an endoscopist who relies on indirect visual information when performing a colonoscopy. Based on past experiences and available knowledge, the sighting of an anatomical landmark during the performance of this procedure may be interpreted to mean that the instrument is situated at a particular location within the colon, when in fact the presence of an anatomical deformity in this patient may render the physician's interpretation as incorrect (Cao and Milgram, 2000). These first exception errors often result in the decomposition of general rules into more specific rule forms and reflect the acquisition of expertise. General rules, however, given their increased likelihood of encounter, usually have higher activation levels in LTM, and under contextual conditions involving high workload and time constraints will be the ones more likely to be invoked.

At the knowledge-based level of performance, needed associations or schemas are not readily available in LTM. Formulating solutions to problems or situations therefore will require intensive WM activity, implying a much greater repertory of behavioral responses and corresponding expressions of error. Contextual factors that include task characteristics and personal factors that include emotional state, risk attitude, and confidence in intuitive abilities can play a significant role in shaping the error modes, making these types of errors much harder to predict. It is at this level of performance that we observe undue weights given to perceptually salient cues or early data, confirmation bias, use of the availability and representative heuristics (especially for assessing relationships between causes and effects), underestimation and overestimation of the likelihood of events in response to observed data, *vagabonding* (darting from issue to issue, often not even realizing that issues are being revisited), and *encysting* (overattention to a few details at the expense of other, perhaps more relevant information).

## 2.2.5 Tendency to Minimize Cognitive Effort

The tendency for the human to minimize cognitive effort is a way of partly explaining shortcuts people unintentionally take in their mental processing, including their use of heuristics. It also explains why many people, especially in the course of their work activities, do not adopt various aiding devices intended to support their activities (Sharit, 2003).

A classic manifestation of this tendency is the reluctance to invest mental resources to peruse service manuals, technical publications, or other forms of documentation, whether printed or computer based, unless left with no option. More palatable options

generally consist of trial-and-error assembly or use of a device or asking a co-worker for help. For example, residents performing morning rounds in intensive care units (ICUs) will often find it easier, especially when under time pressure to process a relatively large number of patients, to obtain needed information concerning patient status from ICU nurses rather than comb through various sources of information for the purpose of constructing mental models of patient problems. Similarly, a mechanic who encounters difficulty when trying to execute an assembly strategy may be inclined to ask a fellow mechanic for assistance, especially if there are a number of impending tasks to be performed.

In contrast to the automatic processing mode that largely characterizes efficient skill-based performance, performance that requires a significant outlay of attention is effortful and potentially exhaustive of information-processing resources. From an evolutionary standpoint, this type of processing leaves us vulnerable: Being consumed with activities requiring *focused* or *divided attention* leaves little capacity for negotiating other environmental inputs that can prove threatening. In practical work situations, especially in contexts with changing conditions and objectives, this type of processing can disable or weaken performance that is based on either *feedforward control*, whereby the human devises strategies or plans for controlling a work process, or *feedback control*, whereby the human monitors and assesses conditions and adjusts or adapts performance according to system outputs.

Most work and, for that matter, everyday situations are, however, characterized by sufficient regularity and predictability to warrant the use of shortcuts in mental processing. In fact, the argument can be made that at any given time the human's normal work performance reflects a subconscious attempt to optimally balance use of these efficient shortcuts with more capacity-demanding mental processing—what Hollnagel (2004) has referred to as the "efficiency-thoroughness trade-off" (ETTO). Because any protective function can fail, it should not be surprising that conditions and events can become aligned in ways that allow shortcuts, heuristics, or expectation-driven behaviors to lead to negative outcomes. Although such outcomes may be due to the momentary existence of conditions that were not favorable to the particular type of ETTO that was manifest, and thus reflect *normal* performance variability, they still derive in part from human fallibility related to the tendency to minimize cognitive effort.

Some typical ETTO rules noted by Hollnagel (2004, p. 154) that characterize how people (or groups of people) cope with particular work situations are as follows:

- *Looks ok*. The worker resorts to a quick judgment rather than a more thorough check of the status and conditions but takes responsibility for the assessment.
- *Not really important*. Even though there are cues to warrant a closer examination of the work issue, the consequences of not dealing with the issue are rationalized as not being that serious.

- *Normally ok, no need to check it now*. The tendency to defer closer examination of an issue is often traded off with the riskier decision resulting from internal or external pressure to meet production goals.
- *It will be checked by someone else later/it has been checked by someone else earlier*. Time pressure and impending deadlines often lead to a lowered criterion for the assumption that someone else will take care or has taken care of the issue.
- *Insufficient time or resources; will do it later*. The perception that there is insufficient time or resources to perform certain activities can create the tendency to minimize the importance or urgency to complete those activities and increase the importance of the activities in which one is currently engaged.
- *It worked the last time around; don't worry, it's perfectly safe and nothing will happen*. Referencing anecdotal evidence, resorting to wishful thinking, and referring to authority or experience rather than facts are all ways of averting more time- and resource-consuming activities that involve checks and closer examination of work processes.

### 2.2.6 Other Aspects of Human Fallibility

There are many facets to human fallibility, and all have the potential to contribute to human error. Peters and Peters (2006) refer to these attributes as "behavioral vectors" and suggest that "the overestimation of human capability (to adapt) and lack of meaningful consideration of individual differences is a prime cause of undesired human error" (p. 47).

One class of individual differences that has not been given sufficient attention with regard to its ability to influence the possibility for human error is personality traits. For example, in many scenarios that involve hand-offs of work operations across shifts, it is essential that the incoming worker receive all pertinent information regarding the work activities that will be inherited. An incoming worker with a passive or submissive personality, however, may be reluctant to interrupt, interrogate, or question the outgoing worker concerning the information that is being communicated or to actively pursue information from that person, especially if that worker is perceived to have an aggressive personality or assumes a higher job status. These situations are more pervasive than one might expect, and whether they involve maintenance personnel in process control industries or medical providers in hospitals, the end result can be the same: The incoming worker may develop an incomplete or incorrect mental model of the problem. This, in turn, could lead to *false assumptions*, for example, about how an assembly procedure may need to be completed or how a new patient arrival into the ICU should be managed.

Personality traits that reflect dispositions toward confidence, conscientiousness, and perseverance could

also influence the possibility for errors. Overconfidence in particular can lead to risk-taking behaviors and has been implicated as a contributory factor in a number of accidents. Similarly, people often can be characterized in terms of having a propensity for taking risks (risk-prone behavior), avoiding risks (risk-averse behavior), or being risk neutral (Clemens, 1996). As implied in Section 2.2.5, these behavioral propensities can impact the criterion by which ETTO rules become invoked.

Another important type of fallibility concerns the human's vulnerability to sleep deprivation and fatigue. These physiological states can often be induced by work conditions and have aroused media attention as possible contributory factors in several high-profile accidents. In fact, in the maritime and commercial aviation industries, conditions of sleep deprivation and fatigue are often attributed to company or regulatory agency rules governing hours of operation and rest time. The effects of fatigue on human performance may be to regress skilled performers to the level of unskilled performers (CCPS, 1994) through widespread degradation of abilities that include decision making and judgment, memory, reaction time, and vigilance. The National Aeronautics and Space Administration (NASA) has determined that about 20% of incidents reported to its Aviation Safety Reporting System (Section 5.4.1), which asks pilots to report problems anonymously, are fatigue related (Kaye, 1999). On numerous occasions pilots have been found to fall asleep at the controls, although they usually wake up in time to make the landing.

An aspect of human fallibility with important implications for human error is *situation awareness* (Chapter 19), which refers to a person's understanding or mental model of the immediate environment (Endsley, 1995). Presumably, any factor that could disrupt a human's ability to acquire or perceive relevant data concerning the elements in the environment, or compromise one's ability to understand the importance of that data and relate them to events that may be unfolding in the near future, can degrade situation awareness. Comprehending the importance of the various types of information in the environment also implies the need for temporal awareness—the need to be aware of how much time tasks require and how much time is available for their performance (Grosjean and Terrier, 1999).

Many factors related to human fallibility and context can potentially influence situation awareness. Increased knowledge (perhaps through training) or expertise (through experience) should allow for better overall assessments of situations, especially under contextual conditions of high workload and time constraints, by enabling elements of the problem and their relationships to be identified and considered in ways that would be difficult for those who are less familiar with the problem. In contrast, poor display designs that make integration of data difficult can easily impair the process of assessing situations. In operations involving teamwork, situation awareness can become disrupted by virtue of the confusion created by the presence of too many persons being involved in activities.

Human limitations in sensory processes and motor movement (Chapters 3, 4) can also contribute to unintended or inadequate outcomes that are often attributed to human error. Because sensory, motor, and cognitive abilities tend to decline with age (Chapter 52), there is the inclination to associate aging with an increased likelihood of human error. However, the literature on aging and work performance is somewhat shaky on this subject (Czaja and Sharit, 2009), and we know that many factors can counteract or compensate for the effects of these declines. Examples of such compensatory factors include the availability of environmental support in the form of memory and other aiding devices; the provision of favorable ergonomic work conditions such as increased illumination levels; continued practice on job activities that are frequently encountered; and the use of knowledge gained from experience to devise more efficient work strategies. The fact that older people usually are more conservative in their estimations of risk, either because of awareness of their physiological declines or as a result of their knowledge accumulated from experience, also tends to mitigate the propensity for their actions to produce adverse outcomes. Declines with age in the speed of cognitive processing, however, suggest that despite such compensatory abilities, older individuals are generally not suitable for work activities that rely heavily on fundamental information-processing abilities.

Finally, the human's vulnerability to a number of affective factors can corrupt human information-processing capabilities and thus predispose the human to error. Personal crises could lead to distractions, and emotionally loaded information can lead to the substitution of relevant job-related information with "information trash." Similarly, a human's susceptibility to panic reactions and fear can impair information-processing activities critical to human performance. Conversely, the tendency to inhibit emotional responses during emergencies can contribute to effective team communication and an increased likelihood of preventing serious accidents.

## 2.3 Context

Human actions are embedded in contexts and can only be described meaningfully in reference to the details of the context that accompanied and influenced them (Dekker, 2005). The attribution and expression of human error will thus depend on the context in which task activities occur.

The notion of a context is not easy to define. Commonly encountered alternative expressions include scenario, situation, situational context, contextual features, contextual factors, and contextual dynamics. Building on a definition of context proposed by Dey (2001) in the domain of context-aware computer applications, *context* is defined as any information that can be used to characterize the situation of a person, place, or object as well as the dynamic interactions among these entities. This definition of context also encompasses information concerning how situations are changing and the human's responses to these situations.

Table 2 lists some representative contextual factors capable of influencing human performance and thus contributing to human errors and violations. Because many of these contextual factors can be described

**Table 2  Contextual Factors Capable of Influencing Human Performance**

| *Attributes of Production Processes* | *Equipment/Interface Design* |
|---|---|
| Degree to which processes are understood | Workspace layout and design |
| Degree to which failed components can be isolated | Personnel protective equipment |
| Degree to which personnel are specialized | Communications equipment |
| Degree to which materials and tools can be substituted | Tool design |
| | Location/access to tools |
| Number of control parameters and interactions among them | Labeling of equipment and supplies |
| | Use of display design principles |
| Degree to which system interdependencies are well defined | Use of control design principles |
| | Design of menus |
| Degree to which system feedback is clear and identifiable | Availability and design of help systems |
| | Availability and design of job aids |
| Degree of slack possible in supplies and equipment | Design of alarms and warnings |
| Degree to which production processes are invariant | Design of voice recognition systems |
| | Demands on memory |

*Work Environment/Work Schedule*

Noise and lighting
Thermal conditions
Vibration and atmospheric conditions
Time constraints
Perceived danger or risks
Interrup
tions and distractions
Suddenness of onset of events
Novel and unanticipated events
Good housekeeping
Work hours and rest breaks
Shift rotation and circadian disruptions

*Job Aids and Procedures*

Designed using task analysis
Instructions are clear and unambiguous
Level of description is adequate
Specification of entry/exit conditions
Instruction is available on their use
Operator feedback on their design
Updated when needed without adding excessive complexity
Capability for referencing procedures during work operations

*Training*

Training in identifying hazardous conditions
Training individuals and teams in using new technologies
Practice with unfamiliar situations
Training on using emergency procedures
Simulator training
Training in interacting with automation
Use of just-in-time training
Ensuring workers have adequate supportive information

*Organization and Social Factors*

Teamwork and communication
Clarity of responsibilities
Clarity in safety–productivity priorities
Authority and leadership
Feedback channels from workers on procedures and policies
Safety culture
Absence of culture of blame and retribution
Management commitment to safety and organizational learning

*Higher Order Factors*

Social, political, and economic factors
Regulatory agency factors

at much greater levels of detail, for any particular domain of application practitioners and analysts would need to determine the appropriate level of contextual analysis.

The presumption is that higher order factors such as sociopolitical or government regulatory factors can influence or shape organizational factors. Organizations, in turn, are assumed to be capable of influencing contextual factors that are more directly linked to human performance. Contexts ultimately derive from the characterization of these factors and the interactions among them. Analysis of the interplay of human fallibility and context as a basis for understanding human error (Section 2.1) will be beneficial to the extent that relevant contextual factors can be identified and analyzed in detail.

A number of quantitative approaches to human reliability analysis (Section 4) employ concepts that are related to context. For example, several of these approaches use *performance-shaping factors* (PSFs) or *influencing factors* (IFs) either to modify the probability estimate assigned to an activity the human performed in error or as the basis for the estimation of that error. These approaches to adjusting or estimating human error probabilities generally assume *additive effects* of PSFs on human performance rather than interactive effects.

Implicit to the concept of a context, however, is the *interactive complexity* among contextual factors with regard to their potential for influencing the reliability of human performance. In this regard, a sociotechnical approach to assessing human reliability

known as STAHR (Phillips et al., 1990) is somewhat more consistent with the concept of a context. STAHR utilizes a hierarchical network of *influence diagrams* to represent the effects of direct influences on human error, such as time pressure and quality of training, as well as the effects of less direct influences, such as organizational and policy issues, which project their influences through the more direct factors.

While STAHR imposes a hierarchical constraint on influences, the dynamic and interactive complexity that underlies the concept of context, in theory, imposes no such constraint. Influences thus could be represented as an *unconstrained network*. Although it may be exceedingly difficult to generate quantitative estimates of human error from such a conceptualization of context, it can still serve as a qualitative tool for the analysis of work contexts and for the prediction of the *possibility* of human errors. To ensure that a manageable number of meaningful contexts are exposed, a defined set of influence mechanisms would need to be imposed on this network structure that could assess the extent to which a contextual factor is present (i.e., the level of activation of a *network node* within the network); the extent to which the factor can influence and be influenced by other factors (i.e., the level of activation of a *network arc*, its direction, and whether the arc's effect is excitatory or inhibitory); and the temporal characteristics underlying these influences.

As the human becomes engaged in setting goals, planning, assessing the situation, and carrying out activities, the possibility for human performance failures or errors would then depend on the interplay—the mutually dependent coupling—between human fallibility, as broadly defined in Section 2.2, and context, conceptualized as a dynamic unconstrained network of contextual factors. In terms of this interplay, the context would influence not only the final external manifestation of the human failure (e.g., activation of the wrong control, performing a soldering operation incorrectly) but also all the precursor conditions (e.g., communication of incorrect or ambiguous information to a co-worker, making an incorrect diagnosis) that could lead to these external error modes.

Knowledge of the existence of these precursor or intermediate states may in fact be of greater interest to organizations as it can be diagnostic of numerous design and process deficiencies and thus provide the basis for an organization's ability to learn (Section 5.4). Moreover, intermediate conditions, such as communication failures, may not lead to observable manifestations of error and adverse consequences only because of barriers, either designed in or a result of fortuitous circumstances, which may have been in place (Section 2.4), but which cannot always be relied on. Many highly instructive but much less formalized accounts of the interplay between human fallibility and context can be found in a number of the reconstructed accidents presented by Stephen Casey (1993, 2006).

The unconstrained network conceptualization of context is similar to the *nonhierarchical* representation of context underlying Hollnagel's (1998) method for human reliability analysis known as CREAM

(Section 4.10). This approach distinguishes between *phenotypes*, which are the external manifestation of erroneous human actions or "error modes," and *genotypes*, which are the factors that can "cause" these failures. Only a limited set of phenotypes are considered, such as an action that is performed too late, is in the wrong direction, is applied to the wrong object, or is omitted. In contrast, a much larger number of genotypes, the possible "causes" of these external "error modes," is proposed, which are categorized according to whether they are person related, technology related, or organization related.

In this scheme, an influence from a factor associated with one category to one or more factors associated with other categories gives rise to "antecedent-consequent" links that reflect cause–effect relationships. The consequents in these links can then serve as the antecedents of yet other categories of factors. The critical analysis lies in the examination of the paths formed by these antecedent-consequent links. The phenotypes are either the starting point in this analytical process, for example, in a *retrospective analysis* of an adverse event, or the endpoint in this analysis, for example, in the *prospective prediction* of the possibility for erroneous actions. Further details related to these concepts are presented in Section 3.2.

Just as contextual factors can be resolved downward to more refined levels of detail, the possibility also exists for describing larger scale work domain contexts that are likewise capable of bringing about adverse outcomes. In this regard, the views of Perrow (1999), which constitute a *system theory of accidents*, have received considerable attention. According to Perrow, the structural analysis of any system, whether technological, social, or political, reveals two loosely related concepts or dimensions: *interactive complexity* and *coupling*. These dimensions have their own characteristic sets of attributes that govern the potential for system accidents and human recovery of these events. Some of the contextual factors corresponding to these attributes are listed in Table 2 under the category "Attributes of Production Processes."

The dimension of interactive complexity can be categorized as either *complex* or *linear* and applies to all possible system components, including people, materials, procedures, equipment, design, and the environment. The relatively stronger presence of features such as increased interconnectivity of subsystems, the potential for unintended or unfamiliar feedback loops, the existence of multiple and interacting controls (which can be administrative as well as technological), the presence of information that tends to be more indirect and incomplete, and the inability to easily substitute people in task activities all serve to predispose systems toward being complex as opposed to linear. Complex interactions are more likely to be produced by complex systems than linear systems. Because these interactions tend to be less perceptible and comprehensible, the human's responses to problems that occur in complex systems can further increase the system's interactive complexity.

Systems also can be characterized by their degree of coupling. Tightly coupled systems are much less tolerant of delays in system processes than are loosely coupled

systems and are much more invariant to materials and operational sequences. Although each type of system has both advantages and disadvantages, loosely coupled systems have greater *slack*, which enables them to more easily absorb the variability of system demands. This attribute provides more opportunities for recovery from events with potentially adverse consequences, often through creative, flexible, and adaptive responses by people. To compensate for the fewer opportunities for recovery that are provided by tightly coupled systems, these systems generally require more built-in safety devices and redundancy than do loosely coupled systems.

Because Perrow's account of technological accidents focuses on the properties of systems themselves rather than human error associated with design, operation, or management of these systems, there has been criticism that his model marginalizes factors at the root of technological accidents (Evan and Manion, 2002). These criticisms, however, do not preclude the possibility of augmenting Perrow's model with additional perspectives on system processes that could endow the model with the capability for providing a reasonably compelling basis for how normal human variability in performance can predispose a system to adverse consequences.

Finally, a contextual factor that can have an especially powerful effect on predisposing the human to error during task performance is *stress*, due to the variety of ways that this phenomenon can influence human fallibility. For example, under stress people tend to become more reluctant to make an immediate decision; seek confirming evidence and disregard disconfirming evidence; become less able to recognize all the alternatives that are available for consideration; offer explanations based on a single global cause rather than a combination of causes; and take greater risks when operating in a group (Kontogiannis and Lucas, 1990).

### 2.4  Barriers

Barriers are entities that are capable of preventing errors or potentially hazardous events from taking place or, if these events manage to occur, can lessen the impact of their consequences. As such, they represent a key construct in the analysis of accidents and in the design of accident prevention systems.

The consideration of barriers was part of the Management Oversight and Risk Tree (MORT) program that was developed for the analysis of accidents and safety programs (Johnson, 1980; Trost and Nertney, 1985; Gertman and Blackman, 1994). MORT relies on a number of tree diagrams to examine factors such as lines of responsibility, barriers toward unwanted energy, and management factors. Its strategies for the elimination of system hazards, in order of importance, largely reflect the use of the following types of barriers: the elimination through design; installation of appropriate safety devices; installation of warning devices; and the use of special procedures. Distinctions between the different purposes of barriers (prevention, control, and minimization of consequences) and types of barriers (physical, equipment design, warning devices,

procedures, knowledge and skills, and supervision) are also proposed within the MORT program.

Human error and barriers are linked in a number of ways. One way in which they are connected relates to whether human actions are capable of becoming classified as human errors. Human actions that fail to result in adverse consequences due to the barriers that were in place may not be conferred with the attribution of human error, even if these actions were capable of generating hazardous conditions. They might instead, at best, be designated as near misses (Section 5.4). If analysts failed to select such actions when conducting human reliability analysis (Section 4.1), the contribution of human–system interactions to system risks could be greatly underestimated as these barriers could fail in ways that were not anticipated.

A second important connection between barriers and human error is that many barriers depend on some type of human intervention, whether it be in their detection or interpretation. Consequently, the presence of that barrier may contribute to defining a context that predisposes the human to commit actions that can produce hazardous conditions or accidents (Section 2.1). Similarly, barriers that allow for their modification, such as turning off alarms, can result in work contexts with hidden dangers that, when suddenly exposed, can define new work contexts with increased human error potential. In some cases, the introduction of a barrier may so thoroughly disturb the nature of work that many new and unanticipated forms of human error can arise (as exemplified in Section 5.1.1).

A third and often overlooked connection between barriers and human error concerns how the perception of barriers, such as intelligent sensing systems and corrective devices, may alter human performance. This connection is based in part on characterizations of human fallibility in terms of *risk attitude*, where individuals who are risk prone or even risk neutral, may be more willing to take risks when they perceive barriers to be in place. Adjusting risk-taking behavior to maintain a constant level of risk is in line with *risk-homeostasis theory* (Wilde, 1982). These adjustments presume that humans are reasonably good at estimating the magnitude of risk, which generally does not appear to be the case. A disturbing implication of this theory is the possibility that some interventions by organizations directed at improving the safety climate (Section 6) could instead result in work cultures that promote attitudes that are nonconducive to safe operations. The real danger of these behaviors is that they can establish new contexts that the barriers were not designed to prevent.

#### 2.4.1  Classification of Barrier Systems

Hollnagel (2004) has proposed a classification of barriers that, for our purposes, can serve to highlight the link between human error and barriers that can arise by virtue of human interaction with the barrier system. In his approach, barrier systems are grouped into four categories: physical or material barrier systems, functional barrier systems, symbolic barrier systems, and incorporeal barrier systems. The possibility also exists

**Table 3  Barrier functions**

| Barrier Function | Example |
|---|---|
| **Barrier Functions for Physical Barrier Systems** | |
| Containing or protecting | Walls, doors, buildings, restricted physical access, railings, fences, filters, containers, tanks, valves, rectifiers |
| Prevent transporting something from the present location (e.g., release) or into the present location (penetration) | |
| Restraining or preventing movement or transportation of mass or energy | Safety belts, harnesses, fences, cages, restricted physical movements, spatial distance (gulfs, gaps) |
| Keeping together; cohesion, resilience, indestructibility | Components that do not break or fracture easily (e.g., safety glasses) |
| Separating, protecting, blocking | Crumble zones, scrubbers, filters |
| **Barrier Functions for Functional Barrier Systems** | |
| Preventing movement or action (mechanical, hard) | Locks, equipment alignment, physical interlocking, equipment match |
| Preventing movement or action (logical, soft) | Passwords, entry codes, action sequences, preconditions, physiological matching (e.g., iris, fingerprint, alcohol level) |
| Hindering or impeding actions (spatial-temporal) | Distance (too far for a single person to reach), persistence (deadman button), delays, synchronization |
| Dampening, attenuation | Active noise reduction, active suspension |
| Dissipating energy, quenching, extinguishing | Air bags, sprinklers |
| **Barrier Functions for Symbolic Barrier Systems** | |
| Countering, preventing, or thwarting actions | Coding of functions (e.g., by color, shape, spatial layout), demarcations, labels, and (static) warnings (facilitating correct actions may be as effective as countering incorrect ones) |
| Regulating actions | Instructions, procedures, precautions/conditions, dialogues |
| Indicating system status | Signs (e.g., traffic signs), signals (visual, auditory), warnings, alarms |
| Permission or authorization (or the lack thereof) | Work permit, work order |
| Communication, interpersonal dependency | Clearance, approval (on-line or off-line) in the sense that the lack of clearance, etc., is a barrier |
| **Barrier Functions for Incorporeal Barrier Systems** | |
| Complying, conforming to | Self-restraint, ethical norms, morals, social or group pressure |
| Prescribing: rules, laws, guidelines, prohibitions | Rules, restrictions, laws (all either conditional or unconditional) |

*Source*: Hollnagel (2004).

for barriers to consist of some composite of these types of systems. A summary of the functions associated with each of these categories of barrier systems is given in Table 3.

### 2.4.2  Paradoxical Effects of Barriers

The possibility for barriers having paradoxical effects was exemplified in a study by Koppel et al. (2005), who found that the introduction of a hospital-computerized physician order entry (CPOE) system, a type of barrier system intended to significantly reduce medication-prescribing errors, actually facilitated errors by users. In this study, errors were grouped into two categories: (1) information errors arising from the fragmentation of data and the failure to integrate information

across the various hospital information systems and (2) human–machine interface flaws that fail to adequately consider the practitioner's behaviors in response to the constraints of the hospital's organizational work structure. An example of an error related to the first category is when the physician orders new medications or modifies existing medications. If current doses are not first discontinued, the medications may actually become increased or decreased or be added on as duplicative or conflicting medication. Detection of these errors was hindered by flaws in the interface that could require 20 screens for viewing a single patient's medications.

Complex organizational systems such as hospitals can make it extremely difficult for designers to anticipate

the many contexts and associated problems that can arise from interactions with the systems that they design (Section 5.1). It may seem to make more sense to have systems such as CPOEs monitored by practitioners and other workers for their error-inducing potential rather than have designers attempt to anticipate all the contexts associated with the use of these systems. However, this imposes the added burden of ensuring that mechanisms are in place for collecting the appropriate data, communicating this information to designers, and validating that the appropriate interventions have been incorporated.

With a number of electronic information devices, the benefits of reducing or even eliminating the possibility for certain types of errors may come at the risk of exposing new windows of opportunity for errors through the alteration of existing contexts. In hospital systems, for example, the reliance on information in electronic form can disturb critical communication flows and is less likely than face-to-face communication to provide the cues and other information necessary for constructing appropriate models of patient problems.

### 2.4.3  Forcing Functions and Work Procedures

A common method often employed by designers for creating barriers to human error is through the use of *forcing functions*, which are design constraints that alert system users to their errors by blocking their actions. For example, computer-interactive systems can force the user to correct an invalid entry prior to proceeding, provide warnings about actions that are potentially error inducing, and employ self-correction algorithms that attempt to infer the user's intentions. Unfortunately, each of these methods can also be breached, depending on the context in which it is used. For example, forcing functions can initiate a process of backtracking by the user that can lead to total confusion and thus more opportunity for error (Reason, 1990), and warnings can be ignored under high workloads.

One of the most frequently used symbolic barrier systems (Table 3) in industry—the *written work procedure*—is also one that is highly vulnerable to misinterpretation, often due to a variety of latent factors. For example, the designers of these procedures may not have adequately considered the human's abilities or users' concerns for their own safety or the work contexts in which the procedure would need to be carried out (Sharit, 1998). Even if procedures are well designed, inadequate training on their execution can provoke actions that can lead to adverse consequences.

Many of the procedures designed for high-hazard operations include warnings, contingencies (information on when and how to "back out" when dangerous conditions arise during operations), and other supporting features. To avoid the recurrence of past incidents, these procedures are often frequently updated. Consequently, they grow in size and complexity to the point where they can contribute to information overload, increasing the possibility even more that their users will miss or confuse important information (Reason, 1997). In addition, procedures that disrupt the momentum of

human work operations will be especially vulnerable to violation.

### 2.4.4  Use of Redundancy for Error Detection

Redundancy in the form of cues presented in multiple modalities is a simple and very effective way of increasing a person's likelihood of detecting and correcting errors. This strategy is illustrated in the case of the ampoule-swap error in hospital operating rooms (Levy et al., 2002). Many drug solutions are contained in ampoules that do not vary much in size and shape, often contain clear liquid solutions, and have few distinguishing features. If an anesthesiologist uses the wrong ampoule to fill a syringe and inadvertently "swaps in" a risky drug such as potassium chloride, serious consequences could ensue. Contextual factors such as fatigue and distractions make it unreasonable to expect medical providers to invest the resources of attention necessary for averting these types of errors. Moreover, the use of warning signs on bins that store ampoules containing "risky solutions" are poor solutions to this problem, as they require that the human maintain *knowledge in the head*—specifically, in WM—thus making this information vulnerable to memory loss resulting from delays or distractions between retrieving the ampoule and preparing the solution. The more reliable solution that was suggested by the investigators of this study was to provide tactile cues on both the storage bins and the ampoules. For example, wrapping a rubber band around the ampoule following its removal from the bin provides an alerting cue in the form of tactile feedback prior to loading the ampoule into the syringe.

Another approach to error detection through redundancy is to have other people available for detecting errors. As with hardware components, human redundancy will usually lead to more reliable systems. However, successful human redundancy often requires that the "other people" be external to the operational situation. Consequently, they would be less likely to be subject to tendencies by people to explain away inconsistencies or evidence that contradict one's assessment of the situation and thus less likely to exhibit *cognitive fixation errors*. In a study of 99 simulated emergency scenarios involving nuclear power plant crews, Woods (1984) found that while none of the errors involving diagnosis of the system state were detected by the operators who made them, other people were able to detect a number of them. In contrast, half the errors categorized as slips (i.e., errors in execution of correct intentions) were detected by the operators who made them.

That barriers to human error based on human redundancy need not always be in place by design is often demonstrated in large-scale hospital systems. In these systems, one typically encounters an assortment of patient problem scenarios, a variety of health care services, complex flows of patient information across various media on a continual 24-h basis, and a large variability in the skill levels of health care providers who must often perform under conditions of overload and fatigue while being subjected to various administrative constraints. Fortunately, there usually exist multiple layers of redundancy in the form of alternative materials

(e.g., equipment), treatment schedules, and health care workers to thwart the serious propagation of many potential errors. Thus, despite a number of constraints that are present in hospital systems, these systems are sufficiently loosely coupled (Section 2.3) to overcome many of the risks that arise in patient care, including those that are generated by virtue of discontinuities or gaps in treatment (Cook et al., 2000).

### 2.4.5 Cognitive Strategies in Error Detection

As implied in the study by Woods (1984), humans are quite adept at detecting and correcting many of the skill-based errors they make, which is why people are often relied upon to serve as barriers. Self-correction, however, implies two conditions: that the human depart from automated processing, even if only momentarily, and that the human periodically invest attentional resources to check whether the intentions are being met and that cues are available to alert one to deviation from intention (Reason, 1990). This would apply to both slips and omissions of actions.

These error detection processes, as well as other error detection processes such as forcing functions or human redundancy, are for the most part relatively spontaneous in nature and do not require significant outlays of effort. At the knowledge-based level of performance, however, the human's error detection abilities are greatly reduced. Error detection in these more complex situations will depend on intensive cognitive processing activities such as the ability to think about possible errors that might occur, predicting the time course of multiple processes, or discovering that the wrong goal has been selected.

Human error detection and recovery at the knowledge-based level of performance may in fact represent a highly evolved form of expertise. Interestingly, whereas knowledge-based errors decrease with increased expertise, skill-based errors increase. Also, experienced workers, as compared to beginners, tend to disregard a larger number of errors that have no work-related consequences, suggesting that with expertise comes the ability to apply higher order criteria for regulating the work system, thus enabling the allocation of attention to errors to occur on a more selective basis (Amalberti, 2001).

Kontogiannis and Malakis (2009) have developed and discuss in detail a taxonomy of cognitive strategies in error detection and identification that is based on the following four stages in error detection:

- *Awareness-Based Detection*. At this stage, introspection is used to critique one's mental models in terms of their completeness, coherence, and reliability, in order to enable revisions of situational assessments to consider hidden and untested assumptions through the collection of additional data.

- *Planning-Based Detection*. These strategies include the consideration of a time scale for revising plans in the face of new evidence; balancing conflicting goals through mental simulation of the risks associated with carrying out alternative plans; regulation of plan complexity to fit

the circumstances; and relying on loosely coupled rather than integrated plans to enable greater flexibility in error detection.

- *Action-Based Detection*. These proactive strategies include running preaction and postaction checks on highly routine tasks in order to avert slips and lapses; creating barriers in the form of reminders to combat the susceptibility to interruptions and "task triggers" to combat capture errors (Section 2.2.4) when tasks need to be performed in a different way; and rehearsing tasks that may need to be carried out later on under time pressure.

- *Outcome-Based Detection*. This stage includes strategies such as examining changes in relational and temporal data patterns over time; cross-checking data to manage mismatches between expected outcomes and observed outcomes; and the use of a mental model to consider the effects of interventions by other agents.

These cognitive strategies for error detection are clearly effortful. For example, they may call for the human to engage in simultaneous belief and doubt or to forego the use of well-used rules in order to cast familiar data in new ways. However, they have important implications for error management training (Kontogiannis and Malakis, 2009) and thus constitute a potentially critical consideration in the development of highly reliable and resilient organizations (Section 6).

## 3 ERROR TAXONOMIES AND PREDICTING HUMAN ERROR

### 3.1 Classifying Human Error

Many areas of scientific investigation use classification systems or taxonomies as a means for organizing knowledge about a subject matter. The subject of human error is no exception. Taxonomies of human error can be used retrospectively to gather data on trends that point to weaknesses in design, training, and operations. They can also be used prospectively, in conjunction with detailed analyses of tasks and situational contexts, to predict possible errors.

Earlier (Section 2.3), a distinction was made between phenotypes, which are the error modes that describe the external (i.e., observable) manifestation of an erroneous action, and genotypes, which are the factors that can influence or "cause" these failures. Eight basic phenotypes, or error modes, have been defined by Hollnagel (1998):

- *Timing*: actions performed too early or too late or omitted

- *Duration*: actions that continued for too long or were terminated too early

- *Force*: actions performed with insufficient or too much force

- *Distance/magnitude*: movements taken too far or not far enough

- *Speed*: actions performed too quickly or too slowly
- *Direction*: movements in the wrong direction or of the wrong kind
- *Wrong object*: a neighboring, similar, or unrelated object used by mistake
- *Sequence*: within a series of actions, actions that were omitted, repeated, reversed in their order, or inappropriately added

When directed at highly specific tasks or operations, this kind of taxonomy can be used to characterize the various ways that a particular task can be performed incorrectly. For example, in the health care industry, the diversity of medical procedures and the variety of circumstances under which these procedures are performed may, in fact, call for highly specific error taxonomies that are derived from more general error classification systems.

For more cognitively complex tasks, it may be useful to classify "cognitive failures." One approach is to categorize these errors in cognition according to stages of information processing (Figure 2), thereby differentiating, for example, errors related to perception from errors related to failures in working memory. The characterization of performance as skill, rule, or knowledge based (Section 2.2.4) also has proven particularly useful in thinking about the ways in which cognitively based failures can arise, in light of the different kinds of information-processing activities that are presumed to be occurring at each of these levels.

Figure 4 and Tables 4 and 5 illustrate several other types of error classification systems. The flowchart in Figure 4 classifies different types of human errors that can occur under SRK levels of performance. This flowchart seeks to answer questions concerning *how* an error occurred. Similar flowcharts are provided by Rasmussen (1982) to address *why* an error occurred as well as *what* type of error occurred.

Reason's (1990) taxonomy (Table 4) also exploits the distinctions among skill, rule, and knowledge-based levels of performance, but draws attention to how error modes related to skill-based *slips* and *lapses* differ from error modes related to rule and knowledge-based *mistakes*. The taxonomy presented in Table 5 illustrates the classification of external error modes into different aspects of information processing.

## 3.2 Predicting Human Error

The use of taxonomies for the purpose of revealing patterns or tendencies related to human performance failures can provide valuable data about weaknesses in design, training, and operations. These classification schemes can also support the gathering of data for performing quantitative human error assessments, which are often required in probabilistic system risk assessments (Section 4.1) and are integral to the analysis of accidents for root causes (Chapter 38).

In addition to these benefits, taxonomies of human error, especially those that emphasize cognitive or causal factors, have predictive value as well. However, as implied in Figure 5, predicting the types of errors humans might commit under actual work conditions is a difficult undertaking. The multidimensional complexity surrounding actual work situations and the uncertainty associated with the human's goals, intentions, and attentional and affective states that unfold over time introduce many layers of guesswork into the process of establishing reliable mappings between human fallibility and situational contexts.

In 1991, Senders and Moray stated: "To understand and predict errors . . . usually requires a detailed task analysis" (p. 60). Very little has changed since then to diminish the validity of this assertion. In fact, our greater understanding of mechanisms underlying human interaction with complex systems (e.g., Woods and Hollnagel, 2005) have probably made the process of predicting human error more laborious than ever, as it should be. Expectations of shortcuts are unreasonable; error prediction by its very nature should be a tedious process and will often be influenced by the scheme selected for error classification.

As implied by Senders and Moray (1991), task analysis (TA) is an essential tool for predicting human error or performance failures. TA describes the human's involvement with a system in terms of the goals to be accomplished and all the human's activities, both physical and cognitive, that are necessary to meet these goals.

Within a TA, the analysis of human–system interactions could be performed using a variety of perspectives and methods. For example, the analyst may resort to simple models of human information processing to determine if the human is receiving sufficiently salient, clear, complete, and interpretable input; has adequate time to respond to the input with respect to being able to mentally code, classify, and resolve the information or in terms of the time the system allows for executing an action; and whether feedback is available to enable the human to determine whether the action was executed correctly and was appropriate for dealing with the goal in question. More complex information-processing schemes can also be used.

These human–system interaction descriptions could also include activity time lines; dependencies that might exist among activities; alternative plans for performing an operation; contingencies that may arise during the course of activities and options for handling these contingencies; characterizations of information flow between different subsystems; and descriptions of displays, controls, training, and interactions with other people. Depending on whether the analysis is to be applied to a process that is still in the conceptual stages, to a newly implemented process, or to an existing process, broad applications of TA techniques that may include mock-ups, walkthroughs, simulations, interviews, and direct observations may be needed to identify the relevant contextual elements.

**Table 4  Human Error Modes Associated with Rasmussen's SRK Framework**

### Skill-Based Performance

| Inattention | Overattention |
| --- | --- |
| Double-capture slips | Omissions |
| Omissions following | Repetitions |
| interruptions | Reversals |
| Reduced intentionality | |
| Perceptual confusions | |
| Interference errors | |

### Rule-Based Performance

| Misapplication of Good Rules | Application of Bad Rules |
| --- | --- |
| First exceptions | Encoding deficiencies |
| Countersigns and | Action deficiencies |
| nonsigns | Wrong rules |
| Informational overload | Inelegant rules |
| Rule strength | Inadvisable rules |
| General rules | |
| Redundancy | |
| Rigidity | |

### Knowledge-Based Performance

| Selectivity | Problems with complexity |
| --- | --- |
| Workspace limitations | Problems with delayed |
| Out of sight, out of mind | feedback |
| Confirmation bias | Insufficient consideration |
| Overconfidence | of processes in time |
| Biased reviewing | Difficulties with |
| Illusory correlation | exponential |
| Halo effects | developments |
| Problems with causality | Thinking in causal series |
| | and not causal nets |
| | Thematic vagabonding |
| | Encysting |

TA can often be enhanced through the use of a variety of auxiliary tools. For example, the analyst may choose to employ checklists that cover a broad range of ergonomic considerations to determine if the human is being subjected to factors (such as illumination, noise, awkward postures, or poor interfaces) that can contribute to erroneous actions. These types of checklists can be expanded to include human fallibility considerations (Section 2.2) and contextual factors (Section 2.3) at various levels of detail.

However, prior to making any such embellishments, it is essential that the analyst identify an appropriate TA method for the particular problem or work domain as a number of different methods exist for performing TA (e.g., Kirwan and Ainsworth, 1992; Luczak, 1997; Shepherd, 2001; Chapter 13). Also, task analysts contending with complex systems will often need to consider various properties of the wider system or subsystem in which human activities take place (Sharit, 1997). As noted by Shepherd (2001), "Any task analysis method which purports to serve practical ends needs to be carried out beneath a general umbrella of systems thinking" (p. 11).

**Table 5  External Error Modes Classified According to Stages of Human Information Processing**

1. Activation/detection
   1.1  Fails to detect signal/cue
   1.2  Incomplete/partial detection
   1.3  Ignore signal
   1.4  Signal absent
   1.5  Fails to detect deterioration of situation
2. Observation/data collection
   2.1  Insufficient information gathered
   2.2  Confusing information gathered
   2.3  Monitoring/observation omitted
3. Identification of system state
   3.1  Plant-state identification failure
   3.2  Incomplete-state identification
   3.3  Incorrect-state identification
4. Interpretation
   4.1  Incorrect interpretation
   4.2  Incomplete interpretation
   4.3  Problem solving (other)
5. Evaluation
   5.1  Judgment error
   5.2  Problem-solving error (evaluation)
   5.3  Fails to define criteria
   5.4  Fails to carry out evaluation
6. Goal selection and task definition
   6.1  Fails to define goal/task
   6.2  Defines incomplete goal/task
   6.3  Defines incorrect or inappropriate goal/task
7. Procedure selection
   7.1  Selects wrong procedure
   7.2  Procedure inadequately formulated/shortcut invoked
   7.3  Procedure contains rule violation
   7.4  Fails to select or identify procedure
8. Procedure execution
   8.1  Too early/late
   8.2  Too much/little
   8.3  Wrong sequence
   8.4  Repeated action
   8.5  Substitution/intrusion error
   8.6  Orientation/misalignment error
   8.7  Right action on wrong object
   8.8  Wrong action on right object
   8.9  Check omitted
   8.10  Check fails/wrong check
   8.11  Check mistimed
   8.12  Communication error
   8.13  Act performed wrongly
   8.14  Part of act performed
   8.15  Forgets isolated act at end of task
   8.16  Accidental timing with other event/circumstance
   8.17  Latent error prevents execution
   8.18  Action omitted
   8.19  Information not obtained/transmitted
   8.20  Wrong information obtained/transmitted
   8.21  Other

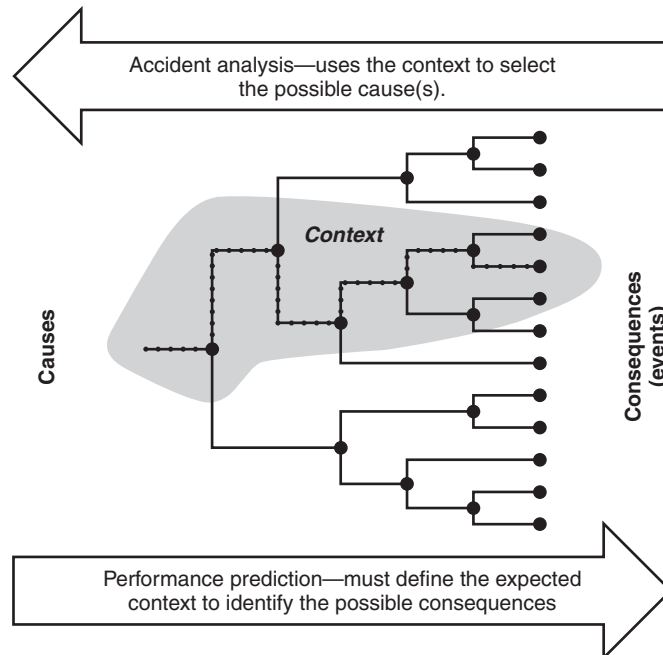

**Figure 5** Backward reasoning from events and context to analysis of causes is a much more constrained process than prediction of events through human actions in context. (From Hollnagel, 1993. Copyright 1993 with permission from Academic Press, Elsevier.)

In cognitive task analysis (CTA), the interest is in determining how the human conceptualizes tasks, recognizes critical information and patterns of cues, assesses situations, makes discriminations, and uses strategies for solving problems, forming judgments, and making decisions. Successful application of CTA for enhancing system performance will depend on a concurrent understanding of the cognitive processes underlying human performance in the work domain and the constraints on cognitive processing that the work domain imposes (Vicente, 1999). In developing new systems, meeting this objective may require multiple, coordinated approaches. As Potter et al. (1998) have noted: "No one approach can capture the richness required for a comprehensive, insightful CTA" (p. 395).

As with TA, many different CTA techniques are presently available (Hollnagel, 2003). TA and CTA, however, should not be viewed as mutually exclusive enterprises—in fact, the case could be made that TA methods that incorporate CTA represent "good" task analyses. With respect to the prediction of errors, generally TA should be capable of uncovering answers to the following questions: What kinds of actions by people are capable of resulting, by one's definition, in errors? What are the possible consequences of these errors? What kinds of barriers do these errors and their consequences call for?

Even when applied at relatively superficial levels, TA techniques are well suited for identifying mismatches between demands imposed by the work context and the human's capabilities for meeting these demands. At this level of analysis, windows of opportunity for error could still be readily exposed that, in and of themselves, can suggest countermeasures capable of reducing risk potential. For example, these analyses may determine that there is insufficient time to input information accurately into a computer-based documentation system; that the design of displays is likely to evoke control responses that are contraindicated; or that sources of information on which high-risk decisions are based contain incomplete or ambiguous information. This coarser approach to predicting errors or error-inducing conditions that derives from analyzing *demand-capability mismatches* can also highlight contextual and cognitive considerations that can form the basis for a more focused application of TA or CTA techniques.

In a type of TA known as a *hierarchical task analysis* (HTA), if the human–system interactions or operations underlying a goal cannot be usefully described or examined, then the goal is reexamined in terms of its subordinate goals and their accompanying plans—a process referred to as "redescription" (Shepherd, 2001). Table 6 depicts a portion of an HTA that was developed for analyzing the task of filling a storage tank with chlorine from a tank truck. The primary purpose of this HTA was to identify potential human errors that could contribute to a major flammable release resulting either from a spill during unloading of the truck or from a tank rupture. From this relatively simple HTA, identifying

**Table 6  Part of a Hierarchical Task Analysis Associated with Filling a Chlorine Tanker**

0.  Fill tanker with chlorine.
    *Plan*: Do tasks 1–5 in order.
1.  Park tanker and check documents (not analyzed).
2.  Prepare tanker for filling.
    *Plan*: Do 2.1 or 2.2 in any order, then do 2.3–2.5 in order.
    2.1  Verify tanker is empty.
        *Plan*: Do in order:
        2.1.1  Open test valve.
        2.1.2  Test for $Cl_2$.
        2.1.3  Close test valve.
    2.2  Check weight of tanker.
    2.3  Enter tanker target weight.
    2.4  Prepare fill line.
        *Plan*: Do in order:
        2.4.1  Vent and purge line.
        2.4.2  Ensure main $Cl_2$ valve is closed.
    2.5  Connect main $Cl_2$ fill line.
3.  Initiate and monitor tanker filling operation.
        *Plan*: Do in order:
    3.1  Initiate filling operation.
        *Plan*: Do in order:
        3.1.1  Open supply line valves.
        3.1.2  Ensure tanker is filling with chlorine.
    3.2  Monitor tanker-filling operation.
        *Plan*: Do 3.2.1, do 3.2.2 every 20 min;
        on initial weight alarm, do 3.2.3 and 3.2.4;
        on final weight alarm, do 3.2.5 and 3.2.6.
        3.2.1  Remain within earshot while tanker is filling.
        3.2.2  Check tanker while filling.
        3.2.3  Attend tanker during last filling of 2 or 3 tons.
        3.2.4  Cancel initial weight alarm and remain at controls.
        3.2.5  Cancel final weight alarm.
        3.2.6  Close supply valve A when target weight is reached.
4.  Terminate filling and release tanker.
    4.1  Stop filling operation.
        *Plan*: Do in order:
        4.1.1  Close supply valve B.
        4.1.2  Clear lines.
        4.1.3  Close tanker valve.
    4.2  Disconnect tanker.
        *Plan*: Repeat 4.2.1 five times, then do 4.2.2–4.2.4 in order.
        4.2.1  Vent and purge lines.
        4.2.2  Remove instrument air from valves.
        4.2.3  Secure blocking device on valves.
        4.2.4  Break tanker connections.
    4.3  Store hoses.
    4.4  Secure tanker.
        *Plan*: Do in order:
        4.4.1  Check valves for leakage.
        4.4.2  Secure log-in nuts.
        4.4.3  Close and secure dome.
    4.5  Secure panel (not analyzed).
5.  Document and report (not analyzed).

external error modes is a relatively straightforward matter.

For example, consider steps 2.3, 3.2.2, 4.1.2, and 4.2.1 in Table 6. Referring to the error classification scheme in Table 5, the manifestation of errors related to each of these actions would occur at the procedure execution stage (stage 8) of information processing:

- For step 2.3 (enter tanker target weight), it would be 8.20: Wrong information obtained, which would lead to entering an incorrect weight.
- For step 3.2.2 (check tanker while filling), it would be 8.9: Check omitted.
- For step 4.1.3 (close tanker valve), it would be 8.18: Action omitted.
- For step 4.2.1 (vent and purge lines), it would be 8.2: Operation incomplete.

Tabular formats are often used to accompany such stepwise task descriptions, allowing for the inclusion of a variety of complimentary assessments. For example, for each task step of a HTA, one column could be assigned to address the possible kinds of performance failures that could arise from these actions; additional columns could be used to document possible causes and consequences of these failures; and still other columns could be directed at error reduction recommendations, which could be further categorized into error mitigation or elimination strategies that resort to procedures, training, or hardware/software (CCPS, 1994) or the use of cognitive error detection strategies (Section 2.4.5).

The taxonomy shown in Table 5 can also be linked to more underlying psychological mechanisms. This would enable errors with identical or similar external manifestations to be distinguished and thus add considerable depth to the understanding of potential errors predicted from the TA. An example of such a scheme is the human error identification in systems technique (HEIST), which classifies external error modes according to the eight stages of human information processing listed in Table 5. The first column in a HEIST table consists of a code whose initial letter(s) refers to one of these eight stages. The next letter in the code refers to one of six general PSFs (Section 2.3): time (T), interface (I), training/experience/familiarity (E), procedures (P), task organization (O), and task complexity (C). These codes can then be linked to external error modes based on various underlying psychological error mechanisms (PEMs). Many of these mechanisms are consistent with the failure modes in Reason's error taxonomy (Table 4).

Table 7 presents an extract from a HEIST table containing a sample of items related to the first two of the eight stages of human information processing listed in Table 5: activation/detection (corresponding to codes beginning with "A") and observation/data collection (corresponding to codes beginning with "O"). More detailed explanations of some of the PEMs listed in the HEIST table are presented in Table 8. A complete HEIST table and the corresponding listing of PEMs can be found in Kirwan (1994).

The human reliability analysis method known as CREAM (Section 4.10) developed by Hollnagel (1998)

**Table 7  Some Items from HEIST Table Corresponding to First Two Stages in Table 5**

| Code | Error Identifier Prompt | External Error Mode | System Cause/Psychological Error Mechanism | Error Reduction Guidelines |
|---|---|---|---|---|
| AT | Does the signal occur at the appropriate time? Could it be delayed? | Action omitted or performed either too early or too late | Signal-timing deficiency, failure of prospective memory | Alter system configuration to present signal appropriately; repeat signal until action has occurred. |
| AI | Is the signal strong and in a prominent location? Could the signal be confused with another? | Action omitted or performed too late or wrong act performed | Signal detection failure | Prioritize signals; place signals in primary location; use diverse signals; use multiple-signal coding; give training in signal priorities; increase signal intensity. |
| AE | Does the operator understand the significance of the signal? | Action omitted or performed too late | Inadequate mental model | Training and procedures should be amended to ensure that significance is understood. |
| AO | Will the operator have a very high or low workload? | Action omitted or performed either too late or too early | Lapse of memory, other memory failure, signal detection failure | Improve task and crew organization; use a recurring signal; consider automation; utilize flexible crewing; enhance signal salience. |
| AC | Is the signal in conflict with the current diagnostic mindset? | Action omitted or wrong act performed | Confirmation bias, signal ignored | Procedures should emphasize disconfirming as well as confirmatory signals; carry out problem-solving training and team training; implement automation. |
| OT | Could the information or check occur at the wrong time? | Failure to act or action performed too late or too early or wrong act performed | Inadequate mental model/inexperience/crew coordination failure | Procedure and training should specify the priority and timing of checks; present key information centrally; utilize trend displays and predictor displays if possible; implement team training. |
| OI | Are any information sources ambiguous? | Action omitted or performed too late or too early or wrong act performed | Misinterpretation, mistakes alternatives | Use task-based displays; design symptom-based diagnostic aids; utilize diverse information sources; ensure clarity of information displayed; utilize alarm conditioning. |
| OE | Could the operator interrogate too many information sources for too long? | Action omitted or performed too late | Thematic vagabonding, risk recognition failure, inadequate mental model | Provide training in fault diagnosis; put procedural emphasis on required data collection time frames; implement high-level indicators (alarms) of system integrity deterioration. |
| OP | Could the operator forget one or more items in the procedures? | Action omitted or performed either too early or too late or wrong act performed | Forget isolated act, slip of memory, place-losing error | Ensure an ergonomic procedure design; utilize tick-off sheets, place keeping aids, etc.; provide team training to emphasize checking by other team member(s). |
| OO | Could information collected fail to be transmitted effectively across shift-handover boundaries? | Failure to act or action is wrong or performed too late or too early or an error of quality | Crew coordination failure | Develop robust shift-handover procedures; training; provide team training across shift boundaries; develop robust and auditable data-recording systems (logs). |
| OC | Does the scenario involve multiple events, thus causing a high level of complexity or a high workload? | Failure to act or wrong action performed or action performed either too early or too late | Cognitive overload | Provide emergency response training; use flexible crewing strategies; develop emergency operating procedures able to deal with multiple transients; generate decision/diagnostic support facilities. |

757

**Table 8  A Sample of Psychological Error Mechanism Descriptions for Some Items in Table 7 and Recommendations for Their Remediation**

*Vigilance failure:* lapse of attention. Ergonomic design of interface to allow provision of effective attention-gaining measures; supervision and checking; task-organization optimization, so that the operators are not inactive for long periods and are not isolated.

*Cognitive/stimulus overload:* too many signals present for the operator to cope with. Prioritization of signals (e.g., high-, medium-, and low-level alarms); overview displays; decision support systems; simplification of signals; flowchart procedures; simulator training; automation.

*Stereotype fixation:* operator fails to realize that situation has deviated from norm. Training and procedural emphasis on range of possible symptoms/causes; fault–symptom matrix as a job aid; decision support system; shift technical advisor/supervision.

*Signal discrimination failure:* operator fails to realize that the signal is different. Improved ergonomics in the interface design; enhanced training and procedural support in the area of signal differentiation; supervision checking.

*Confirmation bias:* operator only selects data that confirm given hypothesis and ignores other disconfirming data sources. Problem-solving training; team training; shift technical advisor (diverse, highly qualified operator who can ''stand back'' and consider alternative diagnoses), functional procedures: high-level information displays; simulator training.

*Thematic vagabonding:* operator flits from datum to datum, never actually collating it meaningfully. Problem-solving training; team training; simulator training; functional procedure specification for decision-timing requirements; high-level alarms for system integrity degradation.

*Encystment:* operator focuses exclusively on only one data source. Problem-solving training; team training (including training in the need to question decisions and in the ability of the team leader(s) to take constructive criticism); high-level information displays; simulator training; high-level alarms for system integrity degradation.

*Source* Adapted from Kirwan (1994).

has, at its core, a method for qualitative performance prediction that is highly dependent on TA. Fundamental to this approach is the distinction referred to in Section 2.3 between phenotypes (Section 3.1), which are the external error modes, and genotypes, which are the possible "causes" of these error modes. Hollnagel presents a large number of tables of genotypes; within each of these tables, the genotype is further resolved into "general consequents," which are, in turn, categorized into "specific consequents." When a general or specific consequent from one genotype can influence the consequents of one or more other genotypes, these initial consequents are considered antecedents. Ultimately, these influences can give rise to chains of antecedent-consequent links. Table 9 lists the consequents associated with the person-related genotype "observation," the technology-related genotype "equipment failure," and the organizational/environment-related genotype "communication."

One problem that can arise using this scheme is the combinatorial explosion of error prediction paths. Hollnagel argues that this potentially large solution space can be logically constrained if the context is sufficiently well known. Toward this end, he suggests using a relatively small set of common performance conditions (CPCs), which he believes contain the general determinants of performance, in order to produce a general context description (Table 10). Although these CPCs are intended to have minimal overlap, they are not considered to be mutually independent.

Using this scheme, the process of human performance or error prediction occurs as follows. First, an analysis of the operator control tasks using TA, as well as analysis of organizational and technical system considerations, is performed. Next, using the CPCs, the context is described. The CPCs serve to "prime" the various classification groups (e.g., Table 9), enabling the more logical or probable antecedent-consequent links, as well as the more likely error modes (Section 3.1), to be specified. The third step consists of specifying the initiating events. These are usually actions humans perform at the "sharp end" (Section 1.1) and are consistent with human actions that are of interest in probabilistic risk assessments (Section 4.1).

The fourth step uses the phenotype–genotype classification scheme to generate propagation paths that lead through the various "causes" of the sharp end's external error mode. The CPCs are used to constrain the propagation paths by allowing the analyst to consider only those consequents that are consistent with the situation; otherwise, the nonhierarchical ordering of the genotype classification groups can produce an excessive number of steps. Phenotypes will always be categorized as consequents as they are the endpoints of the paths.

More recently, an approach to human performance prediction has been proposed that consists of an integration of a number of human factors and system safety hazard analysis techniques (Sharit, 2008). The starting point of this methodology is a TA. The results of the TA become the "human components" of a failure modes and effects analysis (FMEA), a hazard evaluation technique (Kumamoto and Henley, 1996) that in its conventional implementation requires specifying the failure modes for each system component, assembly, or subsystem as well as the consequences and causes of these failure modes. The mapping from the steps of the TA to the possible human performance failures modes essentially results in a "human" FMEA (HFMEA). This process is aided by a classification system in the form of a checklist that considers four broad categories of behavior: perceptual processes (searching for and receiving information and identifying objects, actions, and events); mediational processes (information processing

**Table 9  General and Specific Consequents of Three Genotypes**

| | | |
|---|---|---|
| | ***Person-Related Genotype: "Observation"*** | |
| General Consequent | Specific Consequent | Definition/Explanation |
| Observation missed | Overlook cue/signal | A signal or an event that should have been the start of an action (sequence) is missed. |
| | Overlook measurement | A measurement or some information is missed, usually during a sequence of actions. |
| False observation | False reaction | A response is given to an incorrect stimulus or event, e.g., starting to drive when the light changes to red. |
| | False recognition | An event or some information is incorrectly recognized or mistaken for something else. |
| Wrong identification | Mistaken cue | A signal or a cue is misunderstood as something else. Unlike in a "false reaction," it does not immediately lead to an action. |
| | Partial identification | The identification of an event or some information is incomplete, e.g., as in jumping to a conclusion. |
| | Incorrect identification | The identification of an event/information is incorrect but, unlike in a "false recognition," is a more deliberate process. |
| | ***Technology-Related Genotype: "Equipment Failure"*** | |
| Equipment failure | Actuator stick/slip | An actuator or control either cannot be moved or moves too easily. |
| | Blocking | Something obstructs or is in the way of an action. |
| | Release | Uncontrolled release of matter or energy that causes other equipment to fail. |
| | Speed up/slow down | The speed of the process (e.g., a flow) changes significantly. |
| | No indicators | An equipment failure occurs without a clear signature. |
| Software fault | Performance slowdown | The performance of the system slows down. This can in particular be critical for command and control. |
| | Information delays | There are delays in the transmission of information, hence in the efficiency of communication, both within the system and between systems. |
| | Command queues | Commands or actions are not being carried out because the system is unstable, but are (presumably) stacked. |
| | Information not available | Information is not available due to software or other problems. |
| | ***Organization-Related Genotype: "Communication"*** | |
| Communication failure | Message not received | The message or the transmission of information did not reach the receiver. This could be due to incorrect address or failure of communication channels. |
| | Message misunderstood | The message was received, but it was misunderstood. The misunderstanding is, however, not deliberate. |
| Missing information | No information | Information is not being given when it was needed or requested, e.g., missing feedback. |
| | Incorrect information | The information being given is incorrect or incomplete. |
| | Misunderstanding | There is a misunderstanding between sender and receiver about the purpose, form, or structure of the communication. |

*Source:* Adapted from Hollnagel (1998) by permission of Elsevier.

and problem solving/decision making); communication processes; and motor execution processes.

A well-known disadvantage of FMEAs is their emphasis on single-point failures (e.g., a valve failing open), which increases the likelihood of failing to account for adverse system outcomes deriving from multiple coexisting hazards or failures (U.S. Department of Health and Human Services, 1998). This problem is overcome in the proposed methodology by combining the HFMEA with the hazard and operability (HAZOP) analysis method (CCPS, 1992), a hazard analysis technique that, through creative brainstorming, can enable further insight into possible human–system failures. HAZOP uses a very systematic and thorough approach to analyze points of a process or operation, referred to as "study nodes" or "process sections," by applying, at each point of the process being analyzed, guide words (such as "no," "more," "high," "reverse," "as well as," and "other than") to parameters (such as "flow," "pressure," "temperature," and "operation") in order to generate

**Table 10  Common Performance Conditions**

| CPC Name | Description | Level (Typical ''Values'' They Can Take On) | Expected Effect On Performance Reliability |
| --- | --- | --- | --- |
| Adequacy of organization | The quality of the roles and responsibilities of team members, additional support, communication systems, safety management system, instructions and guidelines, role of external agencies, etc. | Very efficient<br>Efficient<br>Inefficient<br>Deficient | Improved<br>Not significant<br>Reduced<br>Reduced |
| Working conditions | The nature of the physical working conditions such as ambient lighting, glare on screens, noise from alarms, interruptions from the task, etc. | Advantageous<br>Compatible<br>Incompatible | Improved<br>Not significant<br>Reduced |

deviations (such as "no flow" or "high temperature") that represent departures from the design intention. The key to integrating HAZOP with HFMEA is to derive "guide words" and "parameters" that are applicable to the TA.

The proposed methodology also incorporates two additional checklists: One that aids analysts in identifying relevant contextual factors and a second that provides a detailed listing of human tendencies and limitations. Using the first aid, the objective is to assemble, through some form of representation (e.g., through an unconstrained network approach as discussed in Section 2.3), various realistic scenarios that characterize the conditions under which the human performs the activities identified in the TA. Using the second aid, the analytical team would then need to determine which human tendencies or limitations are relevant to the contexts under examination and how these tendencies could result in errors or behaviors that undermine system performance.

Other brainstorming methods, such as what-if analysis, are suggested for analyzing dependencies, such as the impact of human performance failures upon other (impending) human behaviors, and the effects on the system of multiple human failures that may or may not be coupled. Inherent in the methodology is the consideration of barriers that can prevent or mitigate the adverse consequences of the human performance failures or that can promote new previously unforeseen risks.

## 4  HUMAN RELIABILITY ANALYSIS

### 4.1  Probabilistic Risk Assessment

Two sets of tools that analysts often resort to for assuring the safety of systems with hazard potential are (1) traditional safety analysis techniques (CCPS, 1992) such as FMEA (Section 3.2), which utilize primarily qualitative methods, and (2) quantitative risk assessment

procedures (Kumamoto and Henley, 1996), most notably probabilistic risk assessment (PRA). According to Apostolakis (2004), PRAs are not intended to replace other safety methods but rather should be viewed as an additional tool in safety analysis that is capable of *informing* safety-related decision making.

Early on in the development of PRA, analysts recognized that a realistic evaluation of the risks of system operations would require integrating human reliability—the *probability of human failures* in critical system interactions—with hardware and software reliability analysis. In PRA, the objectives of human reliability analysis (HRA) are to identify, represent (within the logic structure of the system or plant PRA), and quantify those human errors or failures for the purpose of determining their contribution to *predetermined* system failures.

In PRAs, it is these failures that are initially specified. For each such consequence or *end state*, disturbances to normal operation, referred to as *initiating events*, are then identified that are capable of leading to these end states. Finally, through plant or system models typically represented as *event trees* or *fault trees* (Section 4.1.1), the sequence of events linking initiating events to end states is developed. The assignment of probabilities to the events leading to accidents ultimately enables the accident scenarios to be ranked according to their risk potential.

The human errors or actions that are considered in a PRA study are often grouped into three categories. The first category consists of *preinitiator* human events. These are actions during normal operations such as faulty calibrations or misalignments that can cause equipment or systems to be unavailable when required. The second category consists of *initiator* human events, which are actions that either by themselves or in combination with equipment failures can lead to initiating events. The third category involves *postfault* human actions. These can include human actions during the accident that, due to the inadequate recognition of the situation or the selection of the wrong strategy, make the situation worse or actions, such as improper repair of equipment, that prevent recovery of the situation.

This categorization of human actions in PRAs highlights the subtle but very important distinction that should be made between human error and human failure, as in some contexts they can have very different meanings. For example, in the category of postfault human actions, following the execution of a particular recovery action there may be insufficient time, through no fault of the human, to perform a subsequent emergency operating procedure.

The catalyst for one of the first HRA methods to be proposed was the problem of nuclear weapons assembly by humans. Alan Swain approached this problem by resorting to detailed task analysis of the steps involved in the assembly process and seeking, through various means, estimates of the probabilities of human errors for each of these steps. This approach was referred to as the technique for human error rate prediction (THERP) and ultimately evolved into a systematic and highly elaborate HRA method that targeted the safety of nuclear power plant operations (Swain and Guttman, 1983).

The WASH 1400 study (1975) led by Norman Rasmussen is often cited as the first formal PRA (Spurgin, 2010). It was directed at investigating accidents resulting from single failures (e.g., a loss of coolant accident) in pressurized and boiling water reactors. This study relied in large part on THERP for deriving human error probabilities (HEPs). Further developments in HRA methods and ways in which they could be incorporated into PRAs involved a number of organizations within the United States such as the U.S. Nuclear Regulatory Commission (NRC), Oak Ridge National Laboratory, and the Electric Power Research Institute (EPRI). Other countries were also making major contributions to HRA (Spurgin, 2010), by either modifying proposed methods or developing new methods.

The use of PRAs in the nuclear industry has also influenced the use of quantitative risk assessment methods in other industries, most notably industries involved in chemical, waste repository, and space operations (Apostolakis, 2004). In addition, other agencies, such as the Environmental Protection Agency, the Food and Drug Administration, and state air and water quality agencies, have also come to embrace NRC-type policies and procedures (Kumamoto and Henley, 1996) and have established their own approaches to assessing risks from human error.

Over the years, HRA has evolved into a discipline that has come to mean different things to different people. This broader perspective to HRA encompasses conceptual and analytic tools needed for understanding how a system's complexity and dynamics can impact human actions and decisions; the appraisal of human errors that may arise within the context of system operations; and design interventions in the form of various barriers that can eliminate or mitigate these negative effects. Within this broader perspective, the choice still remains whether to pursue quantitative estimates of human error probabilities and their contribution to system risks.

An objective assignment of probabilities to human failures implies that HEP be defined as a ratio of the number of observed occurrences of the error to the number of opportunities for that error to occur. Thus, it can be argued that with the possible exception of routine skill-based activities it is questionable whether reliable estimates of HEPs are obtainable. This leaves open the prospect for further diluting the uncertainty that is already implicit to many quantitative system risk assessments such as PRAs.

However, what is often not given sufficient consideration is that the process itself of performing a PRA, irrespective of the precise quantitative figures that they are intended to produce, can provide a number of important benefits (Kumamoto and Henley, 1996; Apostolakis, 2004). Many of the tangible benefits derive from systematic and comprehensive qualitative HRA efforts and can become manifest in the form of improvements in operating procedures in maintenance, testing, and emergency procedures; the kinds of collaborations among workers that are most likely to have safety benefits through redundancy effects; the types of interfaces and

aiding devices that are most likely to improve efficiency during normal operations and response capabilities during emergencies; and clearer identification of areas that would benefit from training, especially in the human's ability to detect, diagnose, and respond to incidents.

Benefits of PRAs of a less tangible nature include improved plant or system knowledge among design, engineering, and operations personnel regarding overall plant design and operations, especially in relation to the complex interactions between subsystems. PRAs also provide a common understanding of issues, thus facilitating communication among various stakeholder groups. Finally, by virtue of their emphasis on quantifying uncertainty, PRAs can better expose the boundaries of expert knowledge concerning particular issues and thereby inform decisions regarding needed research in diverse disciplines ranging from physical phenomena to the behavioral and social sciences.

### 4.1.1  Fault Trees and Event Trees

The two primary hazard analysis techniques that have become associated with PRAs are *fault tree* (FT) analysis and *event tree* (ET) analysis. These techniques can be applied to larger scale system events, for example, as a plant model in a PRA that might include human tasks, or to specified human tasks in order to analyze these tasks in terms of their more elemental task components. The starting point for each of these methods is an undesirable event (e.g., an undesirable system event or an undesirable human task event), whose identification often relies on other hazard analysis techniques (CCPS, 1992) or methods based on expert judgment.

An ET corresponds to an *inductive analysis* that seeks to determine how this undesirable event can propagate into an accident. These trees are thus capable of depicting the various sequences of events that can unfold following the initiating event as well as the risks associated with each of these sequences. Figure 6 depicts a simplified event tree for a loss-of-coolant accident-initiating event in a typical nuclear power plant (Kumamoto and Henley, 1996). The initiating event is a coolant pipe break having a probability (or frequency of occurrence per time period) of $P_A$. The event tree depicts the alternative courses of events that might follow. First, the availability of electric power is considered, followed by the next-in-line system, which is the emergency core-cooling system, whose failure results in the meltdown of fuel and varying amounts of nuclear fission product release depending on the containment integrity.

Figure 7 depicts an ET for an offshore emergency shutdown scenario in a chemical processing scenario. Because it is the sequence of human actions in response to an initiating event that is being addressed, this type of ET is often referred to as an operator action event tree (OAET). In both cases, each branch represents either success (the upper branch) or failure (represented in the OAET as an HEP) in achieving the required actions specified along the top. The probability of each end state on the right is the product of the failure/error or success probabilities of each branch leading to that end state, and the overall probability of any specified failure end state is the sum of the probabilities of the corresponding individual failure end states. In the OAET, the dashed lines indicate paths through which recovery from previous errors can occur.

| A | B | C | D | E | Probability | State |
|---|---|---|---|---|---|---|
| Pipe break | Electric power | ECCS | Fission product removal | Containment integrity | | |
| | | | | Succeeds $\bar{P}_{E1} = 1 - P_{E1}$ | $P_A\bar{P}_B\bar{P}_{C1}\bar{P}_{D1}\bar{P}_{E1}$ | Very small release |
| | | | Succeeds $\bar{P}_{D1} = 1 - P_{D1}$ | Fails $P_{E1}$ | $P_A\bar{P}_B\bar{P}_{C1}\bar{P}_{D1}P_{E1}$ | Small release |
| | | Succeeds $\bar{P}_{C1} = 1 - P_{C1}$ | Fails $P_{D1}$ | Succeeds $\bar{P}_{E2} = 1 - P_{E2}$ | $P_A\bar{P}_B\bar{P}_{C1}P_{D1}\bar{P}_{E2}$ | Small release |
| | | | | Fails $P_{E2}$ | $P_A\bar{P}_B\bar{P}_{C1}P_{D1}P_{E2}$ | Medium release |
| | Succeeds $\bar{P}_B = 1 - P_B$ | Fails $P_{C1}$ | Succeeds $\bar{P}_{D2} = 1 - P_{D2}$ | | $P_A\bar{P}_BP_{C1}\bar{P}_{D2}$ | Large release |
| Initiating event $P_A$ | | | Fails $P_{D2}$ | | $P_A\bar{P}_BP_{C1}P_{D2}$ | Very large release |
| | Fails $P_B$ | | | | $P_AP_B$ | Very large release |

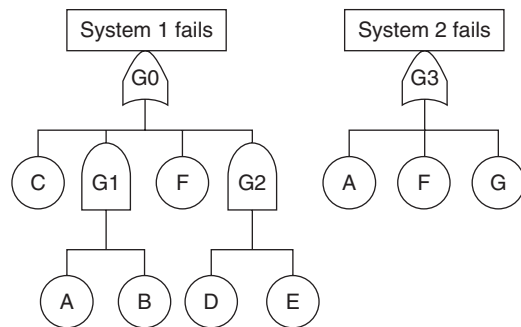
**Figure 6**  Simple event tree for a loss-of-coolant accident with two operator actions and two safety systems. (From Kumamoto and Henley, 1996. Copyright © 2004 by IEEE.)

| S1 begins ESD demand | CCR operator initiates ESD within 20 min | Supervisor initiates ESD within the same 20 min | Operator detects only partial ESD has occured (within 2 h) | Supervisor detects only partial ESD has occured (within 2 h) | CCR operator identifies correct equipment room to outside operator | Outside operator identifies failed activator and communicates these to CCR operator | CCR operator identifies manual valves and tells outside operator | Outside operator moves valves to correct position within the same 2 h | End state |
|---|---|---|---|---|---|---|---|---|---|
| | | | | | | | | | Success |
| | | | | | | | | HEP 1.8 | Failure |
| | | | | | | | HEP 1.7 | | Failure |
| | | | | | | HEP 1.6 | | | Failure |
| | | | | | HEP 1.5 | | | | Failure |
| | | | HEP 1.3 | | | | | | |
| | | | | HEP 1.4 | | | | | Failure |
| | HEP 1.1 | | | | | | | | |
| | | HEP 1.2 | | | | | | | Failure |

**Figure 7** An OAET: ESD, emergency shutdown procedure; CCR, chemical control room. (From Kirwan, 1994.)

In contrast to ETs, an FT represents a *deductive*, top-down decomposition of an undesirable event, such as a loss in electrical power or failure by a human to detect a critical event. In PRAs, FTs utilize Boolean logic models to depict the relationships among hardware, human, and environmental events that can lead to the undesirable *top event*, where HRA is relied upon for producing the HEP inputs. When FTs are used as a quantitative method, *basic events* (for which no further analysis of the cause is carried out) are assigned probabilities or occurrence rates, which are then propagated into a probability or rate measure associated with the top event (Dhillon and Singh, 1981). FTs are also extremely valuable as a qualitative analysis tool, as they can exploit the use of Boolean logic to identify the various combinations of events (referred to as *cut sets*) that could lead to the top event and thus suggest where interventions should be targeted.

The inductive and deductive capabilities of ETs and FTs can go hand-in-hand in PRAs. When combining ETs and FTs, each major column of the ET can represent a top event (i.e., an undesirable event) whose failure probability can be computed through the evaluation of a corresponding FT model. Figure 8 illustrates a simple ET consisting of two safety systems and the two FTs needed to provide probability estimates for the safety system columns in this ET.



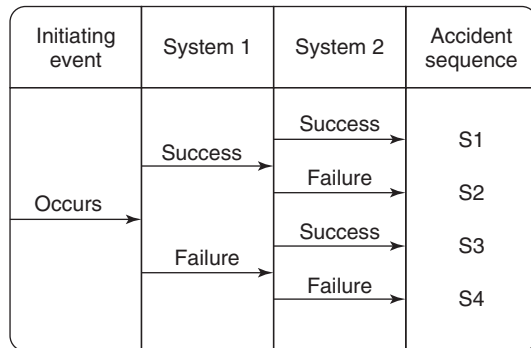


**Figure 8** Coupling of event trees and fault trees. The probabilities of failure associated with systems 1 and 2 in the event tree would be derived from the two corresponding fault tees. (From Kumamoto and Henley, 1996. Copyright © 2004 by IEEE.)

### 4.1.2 HRA Process

The recognition of HRA as a pivotal component of PRA does not necessarily ensure that HRA will be integrated effectively into PRA studies. Given the assumption that human reliability comprises somewhere between 60 and 80% of the total system risk, (e.g., Spurgin, 2010), it is thus imperative that HRA analysts not be excluded from and, ideally, have a substantial involvement in the PRA process.

Recommended practices for conducting HRA can be found in a number of publicly available sources. These include Institute for Electrical and Electronics Engineers (IEEE, 1997) standard 1082 for HRA, American Society for Mechanical Engineers (ASME, 2008) standard for probabilistic risk assessment (ASME STD-RA-S-2008), and the EPRI (1984) systematic human reliability procedure (SHARP; Hannaman and Spurgin, 1984).

It is important to emphasize that these recommended approaches to performing HRA do not imply a specific model for examining human interactions or a particular method for performing HRA and quantification of human errors. The specific needs of the organization will determine the nature of the PRA they wish to perform and thus dictate to some degree the specific HRA model requirements and needed data. However, the influence of the HRA analyst or team should not be discounted, as the biases these individuals have toward approaches to HRA and how these approaches will be implemented can determine, among other things, how contexts will be considered and how human behaviors will be modeled within these work contexts.

The 10-step HRA process proposed by Kirwan (1994) prominently highlights, in its earlier stages, the role of task analysis (Section 3.2) and human error analysis (Figure 9). It is in this respect that HRA can, in principle, be disconnected from PRA and serve objectives directed entirely to qualitative analysis of human error and error prediction (Section 3.2). This does not necessarily preclude quantification of human error, but neither does it imply that such quantification is necessary for identifying and adequately classifying risks to system operations stemming from human–system interactions.

### 4.2 Methods of HRA

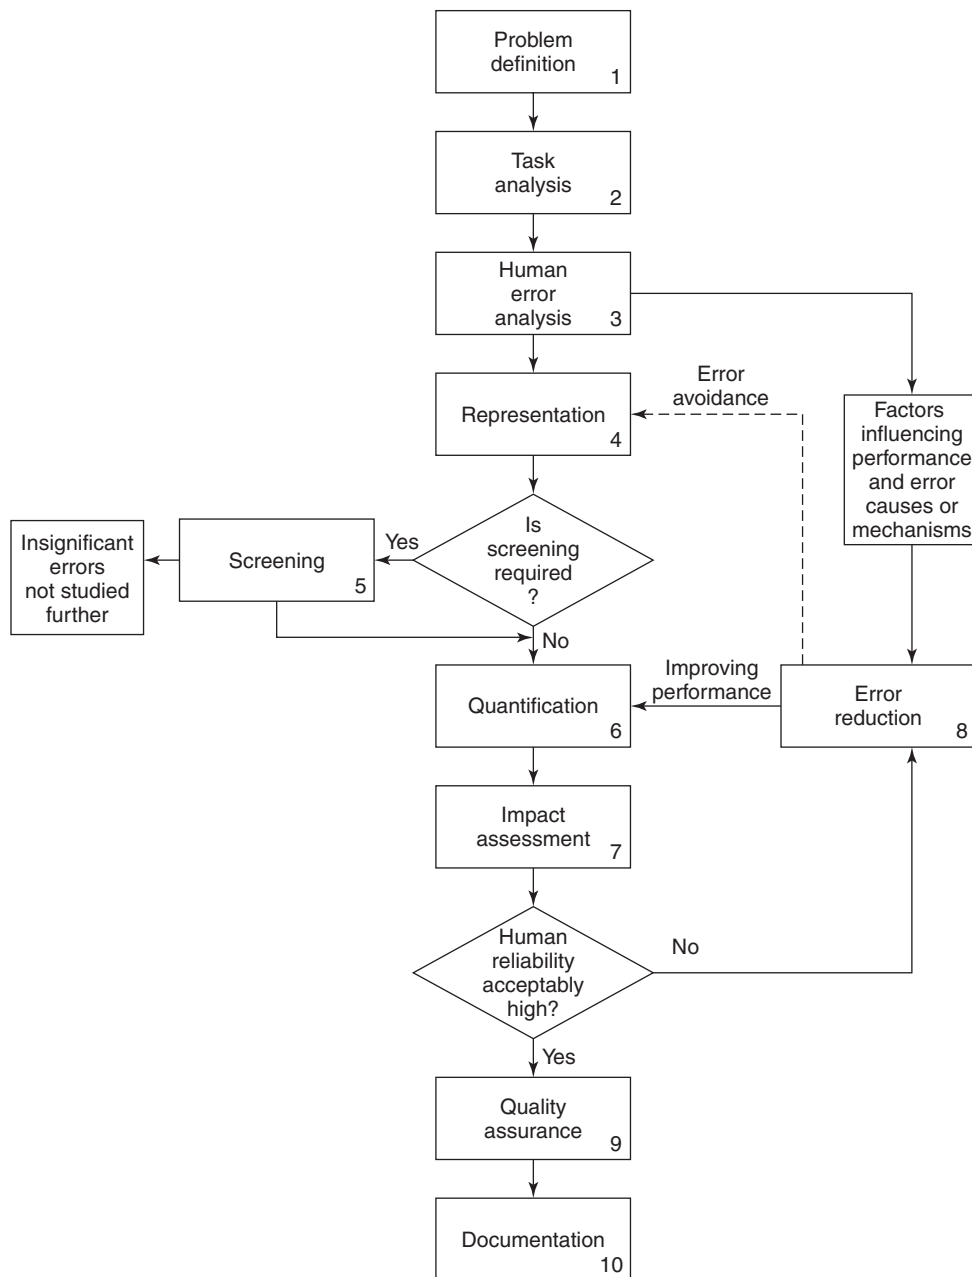
In the ensuing sections, a number of proposed methods of HRA are discussed. Spurgin (2010) has characterized HRA methods into three classes: task related, time related, and context related. Another common classification scheme is to differentiate HRA methods in terms of being first or second generation. Some of the second-generation methods were intended in part to close the gaps of earlier methods (such as THERP) that were lacking in their consideration of human cognition in human error. Regardless of how one chooses to represent HRA methods, one fact that should not go unnoticed is that all methods rely, to some degree, on the use of expert judgment, whether it is to provide base estimates of human error probabilities, identify PSFs and determine their influence on human performance, or assess dependencies that might exist between people, tasks, or events.


**Figure 9** The HRA process. (From Kirwan, 1994.)

Below, a sample of HRA methods is considered, beginning with THERP, which is still the most widely known method. Their discussion will hopefully underscore not only the historical unveiling of needs that motivated the development of alternative HRA methods but also the challenges that this discipline continually faces.

The coverage of these methods will be, by necessity, highly variable as there are many HRA methods that could potentially be considered. In no way is the degree of detail accorded to any HRA method intended to reflect the perceived importance of the method. Also, a number of highly respected methods are not covered at all, which, if anything, points to the challenge of doing this topic justice in a limited space. These methods include a technique for human event analysis (ATHEANA; Forester et al., 2007) and Method d′ Evaluation de la Realisation des Missions Operateur pour la Surete (MERMOS; Pesme et al., 2007).

## 4.3 THERP

The *technique for human error rate prediction*, generally referred to as THERP, is detailed in a work by Swain and Guttmann (1983) sponsored by the U.S. Nuclear Regulatory Commission. Its methodology is largely driven by decomposition and subsequent aggregation: Human tasks are first decomposed into clearly separable actions or subtasks; HEP estimates are then assigned to each of these actions; and, finally, these HEPs are aggregated to derive probabilities of task failure. These outputs could then be used as inputs for the analysis of system reliability (e.g., through the use of a system fault or event tree).

The procedural steps of THERP are outlined in Figure 10. Although these steps are depicted sequentially, in actuality there could be any of a number of feedback loops when carrying out this procedure. The first two steps involve establishing which work activities or events will require emphasis due to their risk potential and the human tasks associated with these activities or events. In steps 3–5, a series of qualitative assessments are performed. Walk-throughs and talk-throughs (e.g., informal interviews) are carried out to determine the "boundary conditions" under which the tasks are performed, such as time and skill requirements, alerting cues, and recovery factors.

Task analysis (Section 3.2) is then conducted to decompose each human task into a sequence of discrete activities. At this stage, it may be opportunistic for the analyst to repeat step 3, with the emphasis this time on encouraging workers to talk through hypothetical, yet realistic, work scenarios for the purpose of assessing the potential for human errors associated with the individual task activities. The analyst may also wish to pursue factors related to error detection and the potential for error recovery.

The results of these efforts are represented by an HRA event tree. In this tree, each relevant discrete task step or activity is characterized by two limbs representing either successful or unsuccessful performance. As indicated in the HRA event tree depicted in Figure 11, the probability that the failure occurs at a particular step in the task sequence is determined by multiplying the product of the probabilities of success on each of the preceding steps by the probability of failure on the step in question. Thus, in Figure 11, the probability that the failure occurs during the execution of step 2 of the task sequence is computed as $F_2 = 0.9898 \times (1 - 0.9845) = 0.0153$. The sum of $F_i, i = 1, \ldots, n$, represents the probability of failure in the performance of this task.

The next set of steps in THERP (steps 6–10) constitutes quantitative assessment procedures. First, HEPs are assigned to each of the limbs of the tree corresponding to incorrect performance. These probabilities, referred to as *nominal HEPs*, in theory are presumed to represent medians of lognormal probability distributions. Associated with each nominal HEP are *upper and lower uncertainty bounds* (UCBs), which reflect the variance associated with any given error distribution. The square root of the ratio of the upper to the lower UCB defines the *error factor* (the value selected for this factor will depend on the variability believed to be associated with the probability distribution for that error). Swain and Guttmann (1983) provide values of nominal HEPs and their corresponding error factors for a variety

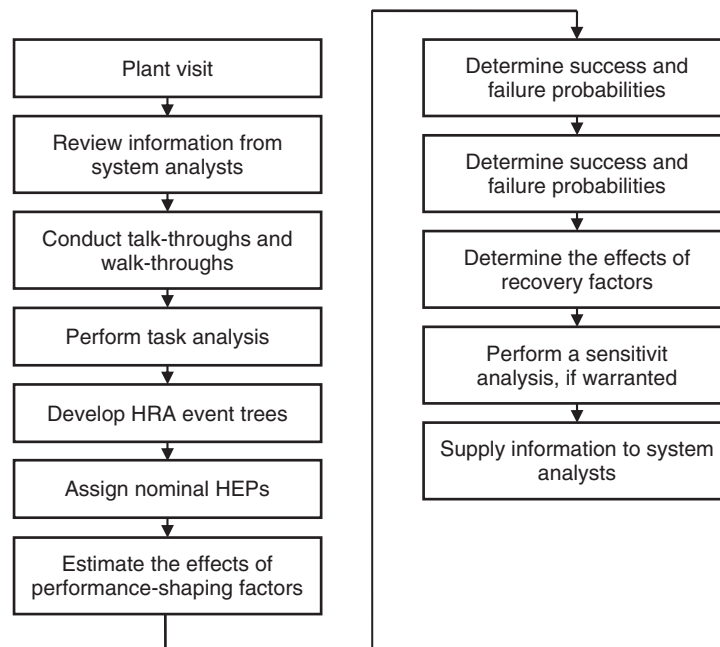

**Figure 10** Steps comprising THERP.

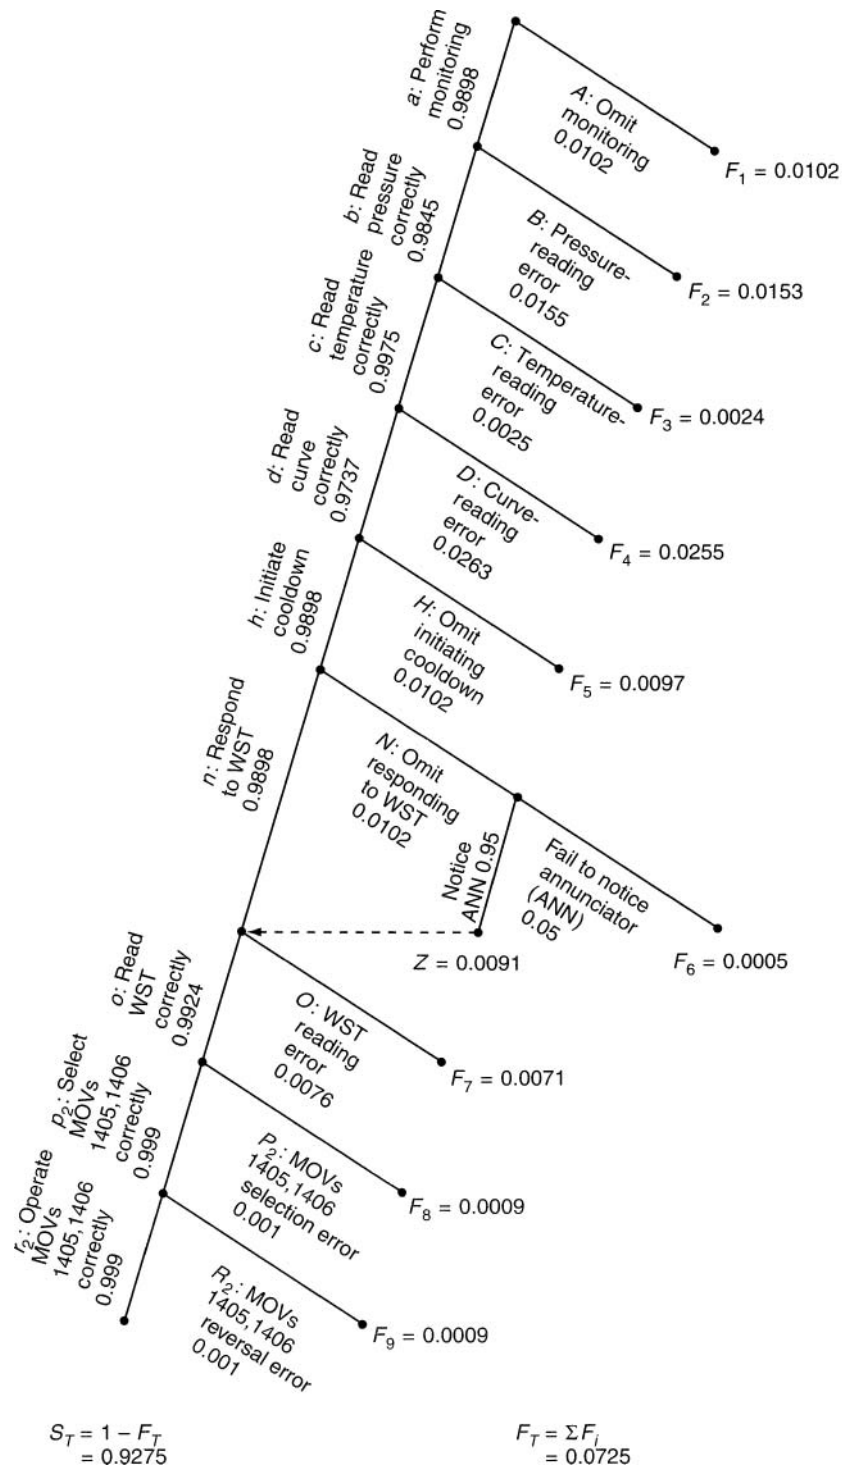
**Figure 11** HRA event tree corresponding to a nuclear power control room task that includes one recovery factor. (From Kumamoto and Henley, 1996. Copyright © 2004 by IEEE.)


of nuclear power plant tasks. Naturally, as technologies evolve and procedures alter, the HEP values provided in such tables become less reliable.

For some tasks the nominal HEPs that are provided refer to *joint HEPs* because it is the performance of a team rather than that of an individual worker that is being evaluated. Generally, the absence of existing hard data from the operations of interest will require that nominal HEPs be derived from other sources, which include (1) expert judgment elicited through techniques such as direct numerical estimation or paired comparisons (Swain and Guttmann, 1983; Kirwan, 1994); (2) simulators (Gertman and Blackman, 1994); and (3) data from jobs similar in psychological content to the operations of interest.

To account for more specific individual, environmental, and task-related influences on performance, nominal HEPs are subjected to a series of refinements. First, nominal HEPs are modified based on the influence of PSFs, resulting in *basic HEPs* (BHEPs). In some cases, guidelines are provided in tables indicating the direction and extent of influence of particular PSFs on nominal HEPs. For example, adjustments that are to be made in nominal HEPs due to the influence of the PSF of stress are provided as a function of the characteristics of the task and the degree of worker experience.

Next, a nonlinear *dependency model* is incorporated which considers positive dependencies that exist between adjacent limbs of the tree, resulting in *conditional HEPs* (CHEPs). In a positive dependency model, failure on a subtask increases the probability of failure on the following subtask, and successful performance of a subtask decreases the probability of failure in performing the subsequent task element. Instances of negative dependence can be accounted for but require the discretion of the analyst. In the case of positive dependence, THERP provides equations for modifying BHEPs to CHEPs based on the extent to which the analyst believes dependencies exist. Five levels of dependency are considered in THERP: zero dependence, low dependence, medium dependence, high dependence, and complete dependence.

For example, assume the BHEP for task step B is $10^{-2}$ and a high dependence exists between task steps A and B. The CHEP of B given failure on step A would be given by the following equation for high dependence: CHEP $= (1 + \text{BHEP})/2 \sim 0.50$. Corresponding equations are given for computing CHEP under low- and medium-dependency conditions. For zero dependence the CHEP reduces to the BHEP ($10^{-2}$ in the example involving step B) and for complete dependence the CHEP would be 1 (failure on the prior task step assures failure on the subsequent step).

At this point, success and failure probabilities are computed for the entire task. Various approaches to these computations can be taken. The most straightforward approach is to multiply the individual CHEPs associated with each path on the tree leading to failure, sum these individual failure probabilities to arrive at the probability of failure for the total task, and then assign UCBs to this probability. More complex approaches to these computations take into account the variability associated with the combinations of events comprising the probability tree (Swain and Guttmann, 1983).

The final steps of THERP consider the ways in which errors can be recovered and the kinds of design interventions that can have the greatest impact on task success probability. Common recovery factors include the presence of annunciators that can alert the operator to the occurrence of an error, co-workers potentially capable of catching or discovering (in time) a fellow worker's errors, and various types of scheduled walkthrough inspections. As with conventional ETs, these recovery paths can easily be represented in HRA event trees (Figure 11). In the case of annunciators or inspectors, the relevant failure limb is extended into two additional limbs: one failure limb and one success limb. The probability that the human responds successfully to the annunciator or that the inspector spots the operator's error is then fed back into the success path of the original tree. In the case of recovery by fellow team members, BHEPs are modified to CHEPs by considering the degree of dependency between the operator and one or more fellow workers who are in a position to notice the error. The effects of recovery factors can be determined by repeating the computations for total task failure.

The analyst can also choose to perform *sensitivity analysis*. One approach to sensitivity analysis is to identify the most probable errors on the tree, propose design modifications corresponding to those task elements, estimate the degree to which the corresponding HEPs would become reduced by virtue of these modifications, and evaluate the effect of these design interventions on the computation of the total task failure probability. The final step in THERP is to incorporate the results of the HRA into system risk assessments such as PRAs.

## 4.4  HEART and NARA

The human error assessment and reduction technique (HEART) proposed by Williams (1988) was an HRA method that was directed at assessing tasks of a more holistic nature based on the assumption that human reliability is dependent upon the generic nature of the task to be performed. Thus the method was relatively easy to apply as, in comparison to THERP, it was not constrained to quantify large numbers of elemental subtasks.

In its emphasis on more holistically appraising the reliability of human task performance, HEART defines a limited set of "generic" tasks (GTs) describing nuclear power plant (NPP) activities from which the analyst can select from. Nominal HEPs (50th percentile) along with lower (5th percentile) and upper (90th percentile) bounds to these estimates are assigned to each of these tasks. For example, one of the generic tasks considered by HEART, together with its corresponding nominal HEP and associated lower and upper bounds is: "Shift or restore systems to a new or original state on a single attempt with supervision or procedures" (0.26; 0.14–0.42).

Although HEART, as in THERP, uses PSFs, referred to as error-producing conditions (EPCs), to modify HEPs, it applies a different approach to this process. In

its consideration of EPCs, HEART emphasizes the practical concern of reliability assessors with the potential for changes in the probability of failure of systems by an order of magnitude of 10. This "factor of 10" criterion is translated into a concern for identifying those EPCs that are likely to modify the probability of task failure by a factor of 3. In HEART's comprehensive listing of EPCs, each EPC is accompanied by an order of magnitude corresponding to the maximum amount by which the nominal HEP might change when considering the EPC at its worst relative to its best state. By providing a battery of remedial measures corresponding to each of the EPCs, HEART also offers a form of closure, by way of design considerations, to the issue of human contribution to system risk. Examples of five of the 38 EPCs along with their associated "orders of magnitude" are:

- A means of suppressing or overriding information or features which is too easily accessible ($\times 9$)
- A need to unlearn a technique and apply one which requires the application of an opposing philosophy ($\times 6$)
- No clear, direct, and timely confirmation of an intended action from the portion of the system over which control is to be exerted ($\times 4$)
- A mismatch between the educational achievement level of an individual and the requirements of the task ($\times 2$)
- No obvious way to keep track of progress during an activity ($\times 1.6$)

The process of computing HEPs in HEART first requires the HRA analyst to match a description of the situation for which a quantitative human error assessment is desired with one of the generic tasks. All relevant EPCs, especially those that satisfy the "factor of 3" criterion, are then identified. Next, the analyst must derive the weighting factor, $\mathrm{WF}_i$, associated with each $\mathrm{EPC}_i$, $i = 1, \ldots, n$, which requires assessing the proportion of the order of magnitude (APOM) associated with each EPC for the generic task being considered. The weighting factor is then defined as

$$\mathrm{WF}_i = [(\mathrm{EPC}_i \text{ order of magnitude} - 1) \times \mathrm{APOM} + 1)]$$

The HEP for the generic task, $\mathrm{GT}_{\mathrm{HEP}}$, is adjusted by multiplying this value by the product of all the weighting factors:

$$\mathrm{HEP} = \mathrm{GT}_{\mathrm{HEP}} \times \sum_{i=1}^{n} \mathrm{WF}_i.$$

NARA (nuclear action reliability assessment) represents a further development of HEART (Kirwan et al., 2005, cited in Spurgin, 2010). This method was partly motivated by concerns with the HEP values associated with the generic tasks in HEART as well as the vagueness of their description, which made the process of selecting generic tasks difficult. The primary differences between NARA and HEART are (1) the dependency on an improved database referred to as CORE-DATA

(Kirwan et al., 1999; Gibson et al., 1999) for HEP values; (2) the inclusion of a set of NARA tasks in place of the set of generic tasks in HEART; and (3) the incorporation of a human performance limit value to address concerns that enhancements in the reliability of human operations can, when human error terms are multiplied together, result in unreasonably low HEPs.

In NARA, the human tasks that are considered are categorized into one of four GT types: (1) type A comprises tasks related to task execution; (2) type B covers tasks related to ensuring correct plant status and availability of plant resources; (3) type C deals with responses to alarms and indicators; and (4) type D tasks involve communication behaviors. The tasks within these GT groups will often be linked so that responses to NARA tasks can come to define more complex tasks. For example, in the case of an accident the initial response may be to type C tasks, which could lead to situational assessment by the crew (type D tasks), and finally various types of execution (type A tasks), possibly following the availability of various systems and components (type B tasks).

Each task within each GT group has an associated HEP value, and EPCs are used, as in HEART, to modify the nominal HEP values. NARA, however, provides much more documentation on the use of EPCs, for example, in the form of anchor values and explanations of these values for each EPC, and guidance in determining the APOM values for each EPC.

## 4.5 SPAR-H

The standardized plant analysis risk human reliability analysis method (SPAR-H) was intended to be a relatively simple HRA method for estimating HEPs in support of plant-specific PRA models (Gertman et al., 2005). The method targets two task categories in NPP operations: action failures (e.g., operating equipment, starting pumps, conducting calibration or testing) and diagnosis activities (e.g., using knowledge and experience to understand existing conditions and making decisions). Although it differs from THERP in a number of its assumptions, THERP's underlying foundation is still very much apparent in SPAR-H. The method works as follows:

*Step* 1. Given an initiating event (e.g., partial loss of off-site power) and a description of the basic event being rated (e.g., the operator fails to restore one of the emergency diesel generators), the analyst must decide whether the basic event involves diagnosis, action, or both diagnosis and action. Guidance is provided to analysts for deciding between these three categories. In SPAR-H, the nominal HEP (NHEP) value assigned to a diagnosis failure is 0.01 and the NHEP assigned to an action failure is 0.001. These base failure rates are considered compatible with those from other HRA methods.

*Step* 2. SPAR-H considers eight PSFs. Each of these PSFs is described in terms of a number of operationally defined levels, including a nominal level.

Associated with each of these levels is a corresponding multiplier that determines the extent of the negative or positive effect the PSF has on the HEP. For some of the PSFs, the definitions of the levels depend on whether an action or a diagnosis is being considered. The eight PSFs are available time; stress/stressors; complexity; experience/training; procedures; ergonomics/human-machine interface; fitness for duty; and work processes. Some of these PSFs in and of themselves encompass a broad array of factors. For example, the PSF "complexity," which refers to how difficult the task is to perform in the given context, considers both task and environment-related factors. Task factors include requirements for a large number of actions, a large amount of communication, high degree of memorization, transitioning between multiple procedures, and mental calculations. The environment-related factors include the presence of multiple faults, misleading indicators, a large number of distractions, symptoms of one fault masking those of another, and ill-defined system interdependencies. It is important to note that in some schemes these could represent separate PSFs.

To illustrate how levels are operationally defined for a PSF, the four levels associated with the "procedures" PSF for an action task are:

- Not available: The procedure needed for the task in the event is not available.
- Task instructions, sections, or other needed information are not contained in the procedure.
- Available, but poor: A procedure is available but it contains wrong, inadequate, ambiguous, or other poor information.
- Nominal: Procedures are available and enhance performance.

In addition, all PSFs have an *insufficient information* level, which the analyst selects if there is insufficient information to enable a choice from among the other alternatives. The assignment of levels denotes ratings of PSFs that translate into multipliers that increase the nominal HEP (i.e., *negative ratings*) or decrease the nominal HEP (i.e., *positive ratings*). The idea that a PSF could reduce the nominal HEP is a departure from HRA methods such as THERP, but some other HRA methods also allow for this possibility (e.g., CREAM, Section 4.9).

*Step* 3. Although the eight PSFs are clearly non-orthogonal, with complex relationships assumed to exist between several of the PSFs, SPAR-H treats these influencing factors as if they were mutually independent. Consequently, to help prevent the analyst from "double counting" when assigning values to the PSFs for the purpose of modifying the nominal task HEP, SPAR-H provides a 64-cell table that contains the presumed degree of correlation among the PSFs based on qualitative rankings of low, medium, or high.

To obtain a composite PSF value, the ratings of the eight PSFs are multiplied by one another, regardless of whether the PSF influence is positive or negative. The HEP is then computed as the product of the composite PSF ($PSF_{composite}$) and the NHEP. Because of the independence assumption and the values ($>1$) that negative PSF ratings can assume, when three or more PSFs are assigned negative rankings, there is a relatively high probability that the resultant HEP would exceed 1.0. In most HRAs, the HEP is simply rounded down to 1.0. To decrease the possibility for HEP values exceeding 1.0, SPAR-H uses the following formula for adjusting the nominal HEP in order to compute the HEP, where NHEP equals 0.01 for diagnosis tasks and 0.001 for action tasks:

$$HEP = \frac{NHEP \times PSF_{composite}}{NHEP \times (PSF_{composite} - 1) + 1}$$

As an example, assume a diagnosis activity (at a nuclear power plant) is required and a review of the operating event revealed that the following PSF parameters were found to have influenced the crew's diagnosis of "loss of inventory": Procedures were misleading; displays were not updated in accordance with requirements; and the event was complex due to the existence of multiple simultaneous faults in other parts of the plant. Assuming these were the only influences contributing to the event, the assignment of the PSF levels and associated multipliers would be:

| PSF | Status | Multiplier |
|---|---|---|
| Procedures | Misleading | ×10 |
| Ergonomics | Poor | ×20 |
| Complexity | Moderately complex | ×2 |

The PSF composite score would be $10 \times 20 \times 2 = 400$. Without an adjustment on the NHEP, the HEP would be computed as NHEP × $PSF_{composite} = HEP = 4.0$. Use of the adjustment factor produces

$$HEP = \frac{0.01 \times 400}{0.01 \times (400 - 1) + 1} = 0.81$$

The adjustment factor can also be applied when a number of positive influences of PSFs are present. In this case, the multiplication factors associated with the "positive" levels of the PSFs would be less than 1.0. However, the SPAR-H PSFs are negatively skewed, so that they have a relatively larger range of influence for negative as compared to positive influences.

*Step* 4. In cases where a series of activities are performed, it is possible that failure on one activity (A) can influence the probability of error on the subsequent activity (B). In THERP, a dependency model consisting of five levels of dependency ranging from no dependency to complete dependency is used to account for such situations

(Section 4.3). SPAR-H also uses these dependency levels. In addition, SPAR-H makes use of a number of factors that can promote dependency between errors in activities performed in series (such as whether the crew is the same or different or whether the current task is being performed close in time to the prior task) to construct a dependency matrix. This matrix yields 16 dependency rules that map, correspondingly, to the four levels where some degree of dependency exists; a 17th rule is used to account for the case of no dependency. The modifications to nominal HEPs resulting from these levels of dependency follow the same procedure as in THERP.

*Step* 5. SPAR-H deals with the concept of uncertainty regarding the HEP estimate, which is the basis for producing lower and upper bounds on the error, very differently than THERP. Whereas THERP assumes HEPs derive from a lognormal probability distribution and uses error factors to derive the lower (5th percentile) and upper (95th percentile) bounds on the error estimate based on this distribution, SPAR-H does not assume a lognormal distribution of HEPs nor does it use error factors.

Instead, SPAR-H uses a "constrained noninformative prior" (CNI) distribution, where the constraint is that the prior distribution (i.e., "starting-point" distribution) has a user-specified mean (which is the product of the composite PSFs and the nominal HEP). The reasons for using this distribution are (1) it takes the form of a beta distribution for probability-type events, which is a distribution that has the flexibility to mimic normal, lognormal, and other types of distributions; (2) unlike THERP, it does not require uncertainty parameter information such as a standard deviation; and (3) it can produce small values at the lower end of the HEP distribution (e.g., $<1 \times 10^{-6}$) but will more properly represent expected error probability at the upper end.

Once the mean HEP is known (i.e., the product of the composite PSFs and the nominal HEP), the starting-point CNI distribution can be transformed to an approximate distribution that is based on the beta distribution. This requires deriving two parameters: $\alpha$ and $\beta$. Tables can be used to obtain values of $\alpha$ for a given value of the mean (which is the HEP), and then this value of $\alpha$ together with the mean can be used to compute $\beta$ using the formula $\alpha(1 - \text{HEP})/\text{HEP}$. Once values of $\alpha$ and $\beta$ are known, various mathematical analysis packages can be used to compute the 5th, 95th, or any percentile desired for the HEP.

*Step* 6. To ensure analyst consistency in using this method, SPAR-H provides designated worksheets to guide the analyst through the entire process required to generate the HEP.

## 4.6 Time-Related HRA Models

HRA models based on time–reliability curves, sometimes referred to as time–reliability correlations (TRCs),

are concerned with the time it takes for a crew to respond to an emergency or accident. The most well-known TRC was the human cognitive reliability (HCR) model (Hannaman et al., 1984) that was sponsored by EPRI based on data obtained from prior simulator studies.

Let $P(t)$ denote the nonresponse probability by a crew to a problem within a given time window $t$, where $t$ is estimated based on analysis of the event sequence following the stimulus. According to the HCR model, this probability can be estimated using a three-parameter Weibull distribution function, a type of distribution applied in equipment reliability models, of the form

$$P_t = e\left[-\left\{\frac{(t/T_{1/2}) - B}{A}\right\}^C\right]$$

where $T_{1/2}$ is the estimated median time to complete the action(s) and $A$, $B$, and $C$ are coefficients associated or "correlated" with the level of cognitive processing required by the crew. Specifically, their values, following Rasmussen's SRK model (Section 2.2.4), depend on whether task performance is occurring at the skill-, rule-, or knowledge-based level.

The variable $t/T_{1/2}$ represents "normalized time," which controls for contributions to crew response times that are unrelated to human activities (Figure 12). Obtaining this normalized time requires defining a "nominal" median response time, $T^n_{1/2}$, which is the time corresponding to a probability of 0.5 that the crew successfully carries out the required task(s) under nominal conditions. Nominal median response times are typically derived from simulator data and talk-throughs with operating crews. The actual (estimated) median response time $T_{1/2}$ is computed from the nominal median response time $T^n_{1/2}$ by

$$T_{1/2} = (1 + K_1)(1 + K_2)(1 + K_3)T^n_{1/2}$$

where $K_1$, $K_2$, and $K_3$ are coefficients whose values depend on PSFs. The HCR model thus assumes that PSFs impact the median response time rather than affect the type of cognitive processing, so that the relationships between the three types of curves remain preserved. The derivation of the estimated median response time from the nominal median response time is illustrated in the following example taken from Kumamoto and Henley (1996, p. 492).

Consider the task of detecting that a failure of an automatic plant shutdown system has occurred. The nominal median response time is 10 s. Assume average operator experience ($K_1 = 0.00$) under potential emergency conditions ($K_2 = 0.28$) with a good operator/plant interface in place ($K_3 = 0.00$). The actual median response time is then estimated to be

$$T_{1/2} = (1 + 0.00)(1 + 0.28)(1 + 0.00)(10) = 12.8 \text{ s}$$

Continuing with this example, assume that the initiating event was loss of feedwater to the heat exchanger that cools a reactor and, due to the failure of the automatic plant shutdown system, manual plant shutdown by the crew is called for. Suppose the crew must
**Figure 12**  HCR model curves. (From Kumamoto and Henley, 1996. Copyright © 2004 by IEEE.)

complete the plant shutdown within 79 s from the start of the initiating event. This time window encompasses not only the time to detect the event, for which the nominal median response time was 10 s, but also diagnosis of and response to the event.

For this example, assume the nature of the instrumentation enables easy diagnosis by control room personnel of the loss-of-feedwater accident and the automatic shutdown system failure, resulting in a nominal median diagnosis time of 15 s. Also, assume errors due to slips (e.g., unintentional activation of an incorrect control) for this procedure are judged to be negligible given the operator–system interface design, so that the nominal median response time can be considered to be 0 s. The total nominal median response time for the shutdown procedure would then be $10 \, \text{s} + 15 \, \text{s} = 25 \, \text{s}$ and, using the $K$ values above, would result in an actual median response time $T_{1/2} = 1.28 \times 25 \, \text{s} = 32 \, \text{s}$. With the level of performance assumed to be at the skill-based level, the corresponding parameter values in the HCR model are $A = 0.407, B = 0.7$, and $C = 1.2$, resulting in a probability that the crew successfully responds to this initiating event within the 79-s window of

$$P[t \leq 79] = e\left[-\left(\frac{(79/32) - 0.7}{0.407}\right)^{1.2}\right] = 0.0029$$

With $K_2 = 0$ (i.e., an optimal stress level), the nonresponse probability would be reduced to 0.00017 per demand for manual shutdown.

The HCR model can also be used to obtain estimates of human or crew failures for more complex operations. Continuing with the example above, the analyst may assume successful plant shutdown occurs but may now be interested in assessing the risks associated with accident recovery, which requires removing heat from the reactor before damage to the reactor is incurred. Suppose there are two options (see below) for coping with the loss of feedwater accident and three different strategies for combining these two options (Kumamoto and Henley, 1996). The different strategies may not only have different time windows but may also involve different levels of cognitive processing as well as distinctive auxiliary human operations. These operations would have associated error probabilities whose values would need to be combined with the results from the HCR model to provide total probabilities of failure for any given strategy.

For example, one strategy, the "anticipatory" strategy, assumes that the crew has concluded that recovery of feedwater through the secondary heat removal system (option 1) is not feasible and decide to establish "feed-and-bleed" (option 2), which involves manually opening pressure-operated relief valves (PORVs) and activation of high-pressure injection (HPI) pumps to exhaust heat to the reactor containment housing. There is a 60-min time window available for establishing the feed-and-bleed operation before damage to the core occurs. Because this operation requires 1 min, the effective time window is reduced to 59 min. If one

assumes well-trained operators ($K_1 = -0.22$), a grave emergency stress level ($K_2 = 0.44$), and good operator interface ($K_3 = 0.00$); a knowledge-based level of performance ($A = 0.791$, $B = 0.5$, and $C = 0.8$); and a nominal median response time of 8 s, $P[t \leq 59] = 0.006$. Assuming the HEP for the manipulation of the PORVs and HPI is 0.001, the HEP for the feed-and-bleed operation is then $0.006 + 0.001 = 0.007$, implying a success probability of 0.993.

However, the success of the anticipatory strategy also hinges on following the feed-and-bleed operation with successful alignment of the heat removal valve system. Kumamoto and Henley (1996) provide a *human reliability fault tree* (in which all the events in the FT are human action events) that computed this top event failure to be 0.0005. Taking a human reliability event tree approach to computing the probability of failure of the anticipatory strategy, this probability has two *failure paths*: (1) failure to perform the feed-and-bleed operation (0.007) and (2) assuming successful performance of this operation (0.993), failure to perform alignment of the heat removal valve system, which is $0.993 \times 0.0005$, resulting in an anticipatory strategy failure of $0.007 + (0.993 \times 0.0005) = 0.0075$.

The validity of the HCR model has been questioned by Apostolakis et al. (1988), who raised the issue of whether the normalized response times for all tasks can be modeled by a Weibull or any other single distribution and the issue of identifying the correct curve due to the fact that many tasks cannot be characterized exclusively as skill, rule, or knowledge based. Following the development of the HCR model, EPRI sponsored a large simulator data collection project (Spurgin et al., 1990) that, in fact, did not confirm a number of the underlying hypotheses associated with HCR model performance.

## 4.7 SLIM

The HRA method SLIM refers to the success likelihood index (SLI) methodology developed by Embrey et al. (1984) for deriving HEPs for specified human actions in NPP operations, although the method is generally believed to be equally as applicable to other industries. SLIM allows the analyst to derive HEPs for relatively low-level actions that cannot be further decomposed as well as for more broadly defined holistic actions that encompass many of these lower level actions.

Underlying SLIM are two premises: (1) that the probability a human will carry out a particular task successfully depends on the combined effect of a number of PSFs and (2) that these PSFs can be identified and appropriately evaluated through expert judgment. For each action under consideration, SLIM requires that domain experts identify the relevant set of PSFs; assess the relative importance (or weights) of each of these PSFs with respect to the likelihood of some potential error mode associated with the action; and, independent of this assessment, rate how good or bad each PSF actually is within the context of task operations.

The first step in SLIM consists of identifying (through the use of experts) the potential error modes associated with human actions of interest and the PSFs most relevant to these error modes. The identification of all possible error modes is generally arrived at through in-depth analysis and discussions that could include task analysis and reviews of documentation concerning operating procedures.

Next, relative-importance weights for the PSFs are derived by asking each analyst to assign a weight of 100 to the most important PSF and then assign weights ranging from 0 to 100 to each of the remaining PSFs based on the importance of these PSFs relative to the one assigned the value of 100. Discussion concerning these weightings is encouraged in order to arrive at consensus weights. Normalized weights are then derived by dividing each weight by the sum of the weights for all the PSFs.

The expert judges then rate each PSF on each action or task, with the lowest scale value indicating that the PSF is as poor as it is likely to be under real operating conditions and the highest scale value indicating that the PSF is as good as it is likely to be in terms of promoting successful task performance. The range of possible SLI values is dictated by the ranges of values associated with the rating scale. As with the procedure for deriving weights, the individual ratings should be subjected to discussion in order to arrive at consensus ratings. The likelihood of success for each human action or task is determined by summing the product of the normalized weights and ratings for each PSF, resulting in numbers (SLIs) that represent a scale of success likelihood.

To illustrate the process by which SLIs are computed, four human actions from the task analysis of the chlorine tanker filling task (Table 6) taken from CCPS (1994) will be considered as indicated in Table 11. When identifying

**Table 11 PSF Ratings, Rescaled Ratings (in parentheses), and SLIs for Chlorine Tanker Filling Example**

| Human Actions | Performance-Shaping Factors | | | | SLIs |
|---|---|---|---|---|---|
| | Time Stress | Experience | Distractions | Procedures | |
| Close test valve (2.1.3) | 4 (0.63) | 8 (0.88) | 7 (0.25) | 6 (0.63) | 0.54 |
| Close tanker valve 4.1.3 | 8 (0.13) | 8 (0.88) | 5 (0.50) | 6 (0.63) | 0.41 |
| Secure locking nuts (4.4.2) | 8 (0.13) | 7 (0.75) | 4 (0.63) | 2 (0.13) | 0.34 |
| Secure blocking device (4.2.3) | 8 (0.13) | 8 (0.88) | 4 (0.63) | 2 (0.13) | 0.35 |
| PSF weights | 0.4 | 0.1 | 0.3 | 0.2 | |

tasks or actions that will be subjected to analysis by SLIM, it is constructive to group activities that are likely to be influenced by the same PSFs, which is considered a legitimate assumption for this set of tasks.

In this example, the main PSFs which determine the likelihood of error are assumed to be time stress, level of operator experience, level of distractions, and quality of procedures. The consensus normalized weights arrived at for these four PSFs are 0.4, 0.1, 0.3, and 0.2, implying that for these tasks time stress is most influential and experience level has the least influence on errors.

Each task is then rated on each PSF. A numerical scale from 1 to 9 will be used, where 1 and 9 represent either best or worst conditions. For the PSFs time stress and distractions, ratings of 9 would represent high levels of stress and distractions and imply an increased likelihood of errors; ratings of 1 would be ideal for these PSFs. In contrast, high ratings for experience and procedures would imply decreased likelihood errors; in the case of these two PSFs, ratings of 1 would represent worst-case conditions. The ratings assigned to each of the four activities are given in Table 11.

To calculate the SLIs, the data in Table 11 are rescaled to take into account the fact that the ideal point (IP) is at different ends of the rating scale for some of the PSFs (either 1 or 9). Rescaling will also serve to convert the range of ratings from 1–9 to 0–1. The formula used to convert the original ratings to rescaled ratings is

$$1 - \frac{ABS\,(R - IP)}{8}$$

where ABS represents the absolute value operator, $R =$ original rating, and IP is the ideal value for the PSF being considered. When the rating is either 1 or 9, this formula converts the original rating to 0.0 or 1.0, as appropriate. The rescaled ratings are shown in parentheses next to the original ratings. Finally, an additive model is assumed whereby the SLI for each task $j$ in Table 11 is calculated using the expression

$$\mathrm{SLI}_j = \sum_{i=1}^{4} \sum_{j=1}^{4} R_{ij}\, \mathrm{PSFw}_i$$

where $\mathrm{PSFw}_j$ is the weight assigned to the $i$th PSF and $R_{ij}$ is the rescaled rating of the $j$th task on the $i$th PSF.

The SLIs represent a measure of the likelihood that the task operations will succeed or fail relative to one another and are useful in their own right. For example, if the actions under consideration represent alternative modes of response in an emergency scenario, the analyst may be interested in determining which types of responses are least or most likely to succeed. However, for the purpose of conducting PRAs, SLIM converts the SLIs to HEPs.

Converting the SLI scale to an HEP scale requires some form of calibration process. In practice, if a large number of tasks in the set being evaluated have known probabilities of error, for example, from internal or industrywide incident data, then the regression equation resulting from the best fitting regression line between the SLI values and their corresponding HEPs can be

used to compute HEPs for other operations in the group for which HEPs are not available. Typically, data sets that enable an empirical relationship between SLIs and HEPs to be computed are not available, requiring the assumption of some form of mathematical relationship. One such assumption is the following loglinear relationship (where logs to base 10 are used) between HEPs and SLIs:

$$\log\,[\mathrm{HEP}] = a \times \mathrm{SLI} + b$$

where $a$ and $b$ are constants. This assumption is partly based on experimental evidence that has indicated a loglinear relationship between factors affecting performance on maintenance tasks and actual performance on those tasks (CCPS, 1994).

To compute the constants in this equation, at least two tasks with known SLIs and HEPs must be available in the set of tasks being evaluated. Continuing with the chlorine tanker filling example, assume evidence was available for arriving at the following HEP estimates for two of the four tasks being evaluated:

- Probability of test valve being left open: $1 \times 10^{-4}$
- Probability of locking nuts not being secured: $1 \times 10^{-2}$

The substitution of these HEP values and their corresponding SLIs into the loglinear equation produces the calibration equation

$$\log\,[\mathrm{HEP}] = -2.303 \times \mathrm{SLI} + 3.166$$

from which the HEPs for the remaining two tasks in the set can be derived:

- Probability of not closing tanker valve: $1.8 \times 10^{-3}$
- Probability of not securing blocking device: $7.5 \times 10^{-3}$

As in THERP, the impact of design interventions can be examined through sensitivity analysis. However, in SLIM, the sensitivity analyses that are performed are based on evaluating the effects of the interventions on PSFs, which result in new SLIs and ultimately new HEPs that can be compared to previous values. In this way, what-if analyses can be used to explore potential design modifications for the purpose of determining which resource allocation strategies provide the greatest reductions in risk potential.

In the absence of HEP data, the calibration values would have to be generated by expert judgment. In these cases, for each task, each expert can be asked to make absolute judgments of the probability of failure associated with two boundary conditions corresponding to situations where the PSFs are as good and as bad as they could credibly be under real operating conditions. These judgments are facilitated through the use of a logarithmic probability scale and are assigned values of 100 and 0, respectively. The SLI computed for a given task is then used to interpolate between these lower

bound (LB) and upper bound (UB) probabilities, which are preferably obtained through consensus, resulting in the following estimate of the HEP for each task:

$$\text{HEP} = \text{LB}^{\text{SLI}/100} \times \text{UB}^{(1-\text{SLI})/100}$$

As PRAs typically require that measures of uncertainty accompany HEP estimates, this direct-estimation approach can also be used to derive these lower and upper uncertainty bounds for the HEP estimates derived by SLIM. In using this approach, the analyst must ensure that the question posed to the expert concerns identifying upper and lower bounds for the HEP such that the true HEP falls between these bounds with 95% certainty.

A user-friendly computer-interactive environment for implementing SLIM, referred to as multi-attribute utility decomposition (MAUD), has been developed which can help ensure that many of the assumptions that are critical to the theoretical underpinnings of SLIM are met. For example, MAUD can determine if the ratings for the various PSFs by a given analyst are independent of one another and whether the relative-importance weights elicited for the PSFs are consistent with the analyst's preferences. In addition, MAUD provides procedures for assisting the expert in identifying the relevant PSFs.

### 4.8 Holistic Decision Tree Method

The holistic decision tree (HDT) method developed by Spurgin (2010) was directed at determining how the context humans find themselves operating in during accident scenarios impacts their failure probability. A detailed example of its application for HRA in various International Space Station (ISS) accident scenarios is given in Spurgin (2010).

Determining the context under which personnel are operating during various ISS accident scenarios requires understanding the relationship between two groups of personnel associated with direct ISS operations: (1) astronauts/cosmonauts, who need to respond to accidents requiring rapid action, control experiments, engage in maintenance activities, and support flight controllers operating from the ground in detecting system anomalies, and (2) flight controllers, who are responsible for monitoring and controlling the ISS systems remotely and on occasion must engage astronauts in debugging activities as controllers are limited in the amount of information available to them.

Some of the concepts associated with the HDT method are related to SLIM and HEART/NARA, especially its emphasis on identifying PSFs as a basis for characterizing the contexts in which humans operate and in evaluating the quality of those PSFs for a given scenario. It also assumes, as in SLIM, a loglinear relationship between an HEP and PSFs. In the HDT method, PSFs are referred to as influence factors (IFs); the ratings of those IFs are referred to as quality values (QVs); and the descriptions on which these QVs are based are referred to as quality descriptors (QDs). As in SLIM, importance weights (i.e., relative rankings) are also determined for each of the IFs. The following steps summarize the process of applying the HDT method (Spurgin, 2010):

*Step* 1. First, a list of potential IFs needs to be identified, which will require HRA analysts becoming familiar with ISS operations. This process will entail detailed reviews of simulator training programs, astronaut operations, and flight controller operations as well as interviews with training staff, astronauts, and controllers. Witnessing training sessions covering simulated accidents is essential. In the ISS study, 43 IFs were initially identified which were ultimately reduced to 6 through interaction with ISS personnel.

*Step* 2. The list of IFs is sorted into scenario-dependent (IFs specific to a particular scenario) or global IFs (which are present in every scenario), as the assumption is that HEPs would be affected by both types of IFs. In the ISS study, all six IFs ultimately identified were global IFs; thus these same IFs were used for all the scenarios considered.

*Step* 3. IFs are then ranked in order of importance, and the most important ones are selected. In this example, the 6 (of the 43) IFs considered (by consensus) to be most important were (1) quality of communication; (2) quality of man–machine interface; (3) quality of procedures; (4) quality of training; (5) quality of command, control, and decision making (CC&DM); and (6) degree of workload. Although these IFs may be very broadly defined, for the purposes of evaluating their QVs, comprehensive yet concise definitions that are clearly linked to the scenarios being evaluated need to be provided for each of these IFs. Examples of these definitions are given by Spurgin (2010).

*Step* 4. Prior to rating the quality of the IFs, QDs need to be defined. In the HDT method, each IF has three possible quality levels, whose descriptions will depend on the IF. For example, in the ISS study, the descriptors for the CC&DM IF were "efficient," "adequate," and "deficient"; for the "quality of procedures" IF the descriptors were "supportive," "adequate," and "adverse"; and for the workload IF the descriptors were "more than capacity," "matching capacity," and "less than capacity." For any given IF, the QDs need to be explicitly defined. For example, for the CC&DM IF, the QD "Deficient" is defined as follows: "Collaboration between (team) members interferes with the ability to resolve problems and return to a desired state of the system."

*Step* 5. Importance weights are derived for each IF. In the HDT method, these weights are obtained through use of the *analytic hierarchy process* (AHP), a mathematical technique developed by Saaty (1980) that has been applied to a wide variety of decision problems. This method requires that each rater rank the relative importance (or preference) of each IF as compared to every other IF. When making these paired comparisons, each IF is given a value from 1 to 9; for example, for a given scenario the relative ranking of communication to procedures may be 6

to 3. The AHP method is amenable to aggregating paired-comparison data from groups of raters and provides estimates of the variability associated with each IF weight that is derived. Among its other advantages are its ability to quantify (and thus ensure) consistency in human judgments; provide empirical results in the absence of statistical assumptions regarding the distribution of human judgments; and its relative ease of administration. In the ISS study, importance weights were derived for five different scenarios for which human performance failure probabilities were of interest: docking, fire, coolant leak, loss of CC&DM, and extravehicular activity (astronauts working in space suits outside the ISS).

*Step* 6. Upper and lower anchor values for the scenario HEP are determined. The upper anchor value may often be assumed to be 1.0, which implies that if all IFs that impact human performance are as poor as possible, it is almost certain that humans will fail. The lower anchor is typically subject to greater variability; thus, each scenario is likely to be assigned a different distribution for the lower anchor value. Spurgin (2010) notes that for most scenarios the 5th percentile of this anchor is set at $10^{-4}$ and the 95th percentile is set at $10^{-3}$; however, for more severe cases, these lower and upper bounds can be set to $10^{-2}$ and 1.0, respectively.

*Step* 7. Using the QDs, each IF is rated for each scenario. In rating each IF, a QV of 1, 3, or 9 is assigned, where 1 represents a "good" quality description, 3 represents a "fair" quality description, and 9 represents a "poor" quality description. Thus a factor of 3 was used to represent ordinal-scale transitions from good to fair and from fair to poor.

*Step* 8. At this point, a decision tree (DT) can be constructed that, for a given scenario, captures the IFs, the importance weights of these IFs, and the three QVs assigned to these IFs. For the six IFs in this example there are a total number of $3^6 = 729$ different paths through this tree, and each path will result in a unique HEP for that scenario. To determine the HEP for a given scenario, the pathway corresponding to the set of QVs that were assigned is located.

*Step* 9. The distribution of HEP values for the different pathways in the DT is derived. For example, consider the portion of the HDT depicted in Figure 13 for a coolant loop leak scenario. The HEPs in the end branches of this tree are computed with the aid of a Microsoft Excel spreadsheet based on the relationship between the IF importance weights, the QVs, and the anchor values. The program provides the ability for quantifying the variance in each IF importance weight and the variances in the lower bound and upper bound anchor values. In Figure 13, the low (anchor) HEP is at the top end branch; increasingly higher values occur as one descends the

tree. In the HDT method, as in SLIM, the log of HEP as a function of IFs is computed, from which HEP values are readily calculated. The HDT method uses the upper and lower HEP anchor values as a basis for deriving HEPs, with the precise expressions used as follows:

$$\ln(\text{HEP}_i) = \ln(\text{HEP}_l) + \ln\left(\frac{\text{HEP}_h}{\text{HEP}_l}\right)\left[\frac{S_i - S_l}{S_h - S_l}\right]$$

$$S_i = \sum_{j=1}^{n}(QV_j)I_j$$

where

$$\sum_{j=1}^{n}I_j = 1$$

In these expressions, $\text{HEP}_i$ is the human error probability of the $i$th pathway through the HDT; $\text{HEP}_l$ is the low HEP anchor value; $\text{HEP}_h$ is the high HEP anchor value; $S_l$ is the lowest possible value of $S_i$ (which equals 1 in the current formulation of QVs for IFs); $S_h$ is the highest possible value of $S_i$ (which equals 9 in the current formulation of QVs for IFs); $QV_j$ is the quality descriptor value (1, 3, or 9 in the current formulation) corresponding to the $j$th IF; and $I_j$ is the importance weight of the $j$th IF.

Overall, the HDT method, like SLIM, is a very flexible method that can be easily adapted to many different types of applications. Also, like SLIM, the impact of changes to influencing factors, which reflects changes in the contexts in which humans operate, can be easily explored and used to assess cost–benefit trade-offs associated with proposed design interventions. However, like SLIM, its success depends on the rigor and skill employed in collecting relevant information regarding operations and the impact of contextual factors on these operations and on generating and managing expert judgments from qualified personnel.

## 4.9  CREAM

The HRA method known as CREAM (cognitive reliability and error analysis method) was developed by Hollnagel (1998). CREAM distinguishes between two methods: a *basic method* and an *extended method*. Both methods result in estimates of the probability of performing an action (either a task as a whole or a segment of a task) incorrectly; in the basic method this estimate is referred to as a general action failure probability and in the extended method this estimate is referred to as a specific action failure probability.

Prior to presenting the basic method, an additional concept that is fundamental to CREAM needs to be introduced, namely, the notion of *control mode*. Hollnagel (1998) has suggested four control modes that are considered important for performance prediction: scrambled control, opportunistic control, tactical control, and strategic control. These different levels of control are influenced by the context as perceived by the person

(e.g., the person's knowledge and experience concerning dependencies between actions) and by expectations about how the situation is going to develop. The distinctions between these four control modes are briefly described as follows:

- *Scrambled Control*. In this mode, there is little or no thinking involved in choosing what to do; human actions are thus unpredictable or haphazard. This usually occurs when task demands are excessive, the situation is unfamiliar and changes in unexpected ways, and there is a loss of situation awareness.

- *Opportunistic Control*. The person's next action is based on the salient features of the current context as opposed to more stable intentions or goals. There is little planning or anticipation.

- *Tactical Control*. The person's performance is based on planning and is thus driven to some extent by rules or procedures. The planning, however, is limited in scope.

● *Strategic Control*. The person considers the global context, using a wider time horizon, and takes into account higher level performance goals.

Initially, as in any HRA method, a task or scenario that will be the subject of the analysis by CREAM needs to be identified. Consistent with most PRA studies, this information is presumably available from lists of failures that can be expected to occur or is based on the requirements from the industry's regulatory body. Following identification of the scenario to be analyzed, the steps comprising the *basic method* of CREAM are as follows.

*Step* 1. The first step involves performing a task analysis (Section 3.1). The TA needs to be sufficiently descriptive to enable the determination of the most relevant cognitive demands imposed by each part of the task and the impact of context, as reflected in CPCs (Section 3.2), on the prediction of performance.

*Step* 2. The next step involves assessing the CPCs. Instead of using an additive weighted sum of CPCs, which assumes independence among the CPCs, CREAM derives a combined CPC score that takes into account dependencies among the CPCs. For example, referring to the CPCs in Table 10, both the "number of simultaneous goals" (the number of simultaneous tasks the person has to attend to at the same time) and "available time" are assumed to depend on the "working conditions." Specifically, improvement in working conditions would result in a *reduction* in the number of simultaneous goals and an *increase* in the available time CPC. Suppose "working conditions" are assessed as "compatible," implying a "not significant" effect on performance reliability (refer to columns 3 and 4 in Table 10).

Then, depending on the effects of other CPCs on "working conditions" (e.g., if they reduce or improve "working conditions"), the assessment of "working conditions" may either remain as "compatible," or be changed to "improved" or "reduced." Using this dependency approach, the synergistic effects of CPCs are taken into account and ultimately (qualitatively) reassessed in terms of their expected effects on performance reliability.

*Step* 3. A combined CPC score is derived by counting the number of times a CPC is expected to (1) reduce performance reliability; (2) have no significant effect; or (3) improve performance reliability. The combined CPC score is expressed as the triplet

$$\left[ \sum\nolimits_{\text{reduced}} \quad \sum\nolimits_{\text{not significant}} \quad \sum\nolimits_{\text{improved}} \right]$$

Not all values are possible when deriving a combined CPC score from these counts. For example, as indicated in Table 10, neither the "number of simultaneous goals" nor the "time of day" can result in an improvement on performance reliability. In the end, there are a total of 52 different combined CPC scores (Figure 14). Among these 52 scores, the triplet [9, 0, 0] describes the least desirable situation (because all 9 CPCs have a "reduced" effect on performance reliability) and the triplet [0, 2, 7] describes the most desirable situation (because the best effect on performance reliability of two of the CPCs is "not significant").

*Step* 4. The final step in the basic method of CREAM is to map this combined CPC score to a general action failure probability. This is accomplished

**Figure 14** Relations between CPC score and control modes. (From Hollnagel, 1998. Copyright 1998 with permission from Elsevier.)

by invoking the concept of "control mode" and creating a plot (Figure 14) that serves a function similar to that of the *risk assessment matrix*, a tool used to conduct subjective risk assessments in hazard analysis (U.S. Department of Defense, 1993). Depending on the region within the plot where 1 of the 52 values of the combined CPC score falls, the human is assumed to be performing in one of the four control modes. For example, the scrambled control mode is represented by the four cases where $\sum_{improved} = 0$ and $\sum_{reduced} = >5$.

While there may be a number of different ways to map the four control modes to corresponding human reliability intervals, Hollnagel (1998) offers one particular set of such intervals. For example, for the strategic control mode, the interval comprising the probability ($p$) of an action failure is [0.5E-5 < $p$ < 1.0E-2], whereas for the scrambled control mode this interval would be [1.0E-1 < $p$ < 1.0E-0], implying the possibility for a probability of failure as high as 1.0.

CREAM's *extended method*, like its basic method, is also centered on the principle that actions occur in a context. However, it offers the additional refinement of producing specific action failure probabilities. Thus, different actions or task segments that may fall into the same control mode region would, in principle, have different failure probabilities. The extended method shares a number of the same features as the basic method, in particular the initial emphasis on task analysis and the evaluation of CPCs. However, to generate more specific action failure probabilities, it incorporates the following layers of refinements:

*Step* 1. The first step is to characterize the task segments or steps of the overall task in terms of the cognitive activities they involve. The goal is to determine if the task depends on a specific set of cognitive activities, where the following list of cognitive activities is considered: coordinate, communicate, compare, diagnose, evaluate, execute, identify, maintain, monitor, observe, plan, record, regulate, scan, and verify. The method recognizes that this list of cognitive activities is not necessarily complete or correct. It also acknowledges the important role that judgment plays in selecting one or more of these cognitive activities to characterize a task step and recommends documenting the reasons for these assignments.

*Step* 2. A *cognitive demands profile* is then created by mapping each of the cognitive activities into four broad cognitive functions. These four functions are observation, interpretation, planning, and execution (which correspond to the three stages of information processing depicted in Figure 2). For example, the cognitive activity "evaluation" is described in terms of the cognitive functions "interpretation" and "planning"; the cognitive activity "coordinate" refers to the cognitive functions "planning" and "execution"; and

the cognitive activity "monitor" refers to the cognitive functions "observation" and "interpretation." Although some cognitive activities (e.g., "diagnose" and "evaluate") may both refer to the same cognitive functions ("interpretation" and "planning"), they are considered distinct because they refer to different task activities during performance. For example, during diagnosis, the emphasis may be on reasoning whereas during evaluation the emphasis may be on assessing a situation through an inspection operation.

Following the description of each cognitive activity in terms of its associated cognitive functions, a cognitive demands profile can be constructed by counting the number of times each of the four cognitive functions occurs. This can be done for each of the task segments or for the task as a whole. A cognitive demands profile plot can then be generated, for example, by listing each task segment on the $x$ axis, and the corresponding relative percentages to which each of the cognitive functions is demanded by that segment.

*Step* 3. Once a profile of cognitive functions associated with the task segments has been constructed, the next step is to identify the likely failures associated with each of these four cognitive functions. In principle, the basis for determining these failures should derive from the complete list of phenotypes (Section 3.1) and genotypes (e.g., Table 9), but for practical purposes, a subset of this list can be used. Thus, for each of the four cognitive functions, a number of potential failures are considered. For example, for the cognitive function "observation," three observation errors are taken into account: observation of wrong object, wrong identification made, and observation not made. Similarly, a subset of interpretation (3), planning (2), and execution (5) errors are considered corresponding to the other three cognitive functions, resulting in a total of 13 types of *cognitive function failures*.

Clearly, if a different set of cognitive functions is identified for use in this HRA model, then a set of cognitive function failures corresponding to those cognitive functions would need to be selected. In any case, given the knowledge of the task and of the CPCs under which the task is being performed, for each task segment the analyst must assess the likely failures that can occur. Note that the distribution of cognitive function failures for each task segment may look very different than the cognitive demands profile distribution, largely because of the impact that performance conditions (i.e., context) are believed to be having. Thus, a task segment may have a larger percentage of cognitive functions associated with observation than interpretation, but following the assessment of cognitive function failures may show a larger number of interpretation failures.

*Step* 4. Following the assignment of likely cognitive function failures to each task segment, the next step involves computing a cognitive failure

probability for each type of error that can occur. These cognitive failure probabilities (CFPs) are analogous to HEPs. Using a variety of different sources, including Swain and Guttmann (1983) and Gertman and Blackman (1994), nominal values as well as corresponding lower (0.05) and upper (0.95) bounds are assigned to these CFPs. For example, for the observation error "wrong identification made," the nominal CFP given is 7.0E-2, and the corresponding lower and upper bound estimates are [2.0E-2, 1.7E-2].

*Step* 5. Next, the effects of CPCs on the nominal CFPs are assessed. The computation of the CPC score that was part of the basic method of CREAM is used to determine which of the four control modes is governing performance of the task segment or task. The nominal CFP is then adjusted based on weighting factors associated with each of these control modes. For the scrambled, opportunistic, tactical, and strategic control modes, the four corresponding weighting factors that are specified are $[2.3E + 01, 7.5E + 00, 1.9E + 00, 9.4E-01]$. These adjustments imply, for example, multiplying the CFP value by 23 if the control mode is determined to be "scrambled" and multiplying the CFP by 0.94 if the control mode is determined to be "strategic."

*Step* 6. If the analyst wishes to reduce the uncertainty associated with adjusting nominal CFPs based on the control mode that is governing performance, a more complex approach can be used. This approach requires that couplings between the nine CPCs and the four cognitive functions (observation, interpretation, planning, and execution) be established by assigning, to each CPC, a "weak," medium, or "strong" influence on each cognitive function. These influences are inherent to the CPCs. For example, the CPC "availability of procedures" would be expected to have a strong influence on the cognitive function "planning," as planning what to do would depend on what alternatives are available, which are presumably described in the procedures. However, this CPC would be expected to have a weak influence on "interpretation" (presumably because procedures do not provide such elaboration). Using similar logic, the CPC "working conditions" would be expected to have a weak influence on "planning" but a medium influence on "observation."

The nominal CFPs and their corresponding lower and upper bounds are then adjusted by weighting factors that are derived as follows. First, the CPC table (Table 10) is consulted to determine whether each CPC is expected to have an effect on performance reliability (if the effect is assessed to be "not significant," then the weighting factor is 1, implying no modification of the nominal CFP). If the CPC is expected to have an effect on performance reliability, then the couplings that were established between the CPCs and the four cognitive functions are used to moderate those effects accordingly; in the

case where the coupling between a CPC and a cognitive function was deemed "weak," then a weight of 1 is assigned.

Ultimately, based on various sources of knowledge, weighting factors are assigned to each of the four cognitive functions for each CPC level, and these weights are used to adjust the original nominal CFPs of the 13 types of failures that were classified according to the type of cognitive function required. For example, for the error type "wrong identification," which is one of the three error types classified under the cognitive function "Observation," consider the CPC "working conditions." Further, consider the three levels of this CPC: advantageous, compatible, and incompatible. For the cognitive function "observation," the weighting factors that would be used to adjust the nominal CFP for the "wrong identification" error type, which is 7.0E-2, are 0.8, 1.0, and 2.0, respectively. Thus, if the CPC is indeed evaluated to be advantageous, the nominal CFP would be adjusted down from 0.07 to $0.8 \times 7.0E-2 = 0.056$, whereas if the CPC is evaluated to be incompatible, the CFP would be adjusted up to $2 \times 7.0E-2 = 0.14$. The lower and upper bounds would be adjusted accordingly. No adjustment would be made if the CPC is evaluated to be compatible.

*Step* 7. Continuing with the example above, in reality, the other eight CPCs could also have an effect on the cognitive function of "observation" and thus on the "wrong identification" observation error. Referring to Table 10, assume the evaluations of the nine CPCs, from top to bottom, were as follows: inefficient, compatible, tolerable, inappropriate, matching current capacity, adequate, daytime, inadequate, and efficient. The corresponding weighting factors would be [1.0, 1.0, 1.0, 2.0, 1.0, 0.5, 1.0, 2.0, 1.0]. The total effect of the influence from the CPCs for this error type is determined by multiplying all the weights, which results in a value of 2.0. The nominal CFP of 7.0E-2 would then be multiplied by 2, resulting in an overall adjusted CFP of $14.0E-2 = 0.14$. If a task is comprised of a number of task segments, the one or more errors that could occur in each segment would be determined in the same way.

*Step* 8. The final step in the extended method of CREAM involves incorporation of the adjusted CFPs into a PRA. This requires providing a single quantitative estimate of human error for the task. If the method was applied to an entire task, the resulting CFP would be used. However, if the method was applied to a number of task segments comprising a task, for example, a sequence of task steps that could be described through a HTA, then the task CFP required for input to the PRA would be based on the component CFPs.

In a fault tree representation of the HTA, if a task requires that a number of component substeps *all* be performed correctly, then any

substep performed incorrectly would lead to failure; under these disjunctive (i.e., logical OR) conditions, the error probability for the step can be taken as the maximum of the individual substep CFPs. If, however, a task step requires only one of a number of component substeps to be performed correctly for the task step to be successful, then only if all the substeps are performed incorrectly would the task step fail; under these conjunctive (i.e., logical AND) conditions, the error probability for the step can be taken as the product of the individual substep CFPs.

## 4.10 HRA Methods: Concluding Remarks

### 4.10.1 Benchmarking HRA Methods

There are a number of ways in which HRA methods can be evaluated and compared—that is, "benchmarked." In a recent article, lessons learned from benchmarking studies involving a variety of other types of methods, as well as issues associated with HRA benchmarking studies, were reviewed for the purpose of ensuring that important considerations were accounted for in planning future HRA benchmarking studies (Boring et al., 2010).

Validation in HRA benchmarking studies is often based on some objective performance measure, such as the probability of human error, against which the corresponding estimates of the HRA methods can be compared. However, even such comparisons can be problematic as different HRA methods may have different degrees of fit to the task or scenario chosen for analysis. Emphasis thus also needs to be given to the diversity of "product" areas—the different kinds of tasks, scenarios, or ways in which the HRA method can analyze a situation—for which these methods are best suited in order to more fully evaluate their capabilities.

In addition to the focus on end-state probabilities generated by the different methods, evaluations in benchmarking studies should also be directed at the qualitative processes that led to those probabilities, including assumptions underlying the method, how PSFs are used, how tasks or scenarios are decomposed, and how dependencies are considered. Comparisons of HRA methods based on other qualitative considerations (e.g., the degree of HRA expertise needed or resources required to use the method), while inherently subjective, can still reveal strengths and weaknesses that can greatly influence the appropriateness of an HRA method for a particular problem (Bell and Holyroyd, 2009).

The inconsistency among analysts in how scenarios or tasks are decomposed for analysis is a particular concern in HRA benchmarking studies and may be partially accountable for low interrater reliability in HEP calculations among analysts using the same HRA method (Boring et al., 2010). Benchmarking studies thus could benefit from frameworks for comparing qualitative aspects of the analysis as well as from uncertainty information (in the form of lower and upper uncertainty bounds on HEPs) to allow comparisons of the range of the HEPs computed.

In Kirwan's (1996) quantitative validation study of three HRA methods, 10 different analysts assessed each of the methods for 30 human error scenarios derived from the CORE database (Sections 4.4 and 4.10.3). Although a generally strong degree of consistency was found between methods and across analysts, no one method was sufficiently comprehensive or flexible to cover a wide range of human performance scenarios, despite the exclusion of scenarios requiring knowledge-based performance (Section 2.2.4) or diagnostic tasks performed by operating crews. Comparing HRA methods on such tasks and on scenarios in domains other than nuclear power remains a challenge for HRA benchmarking studies (Boring et al., 2010).

### 4.10.2 Issue of Dependencies

A challenging problem for all HRAs is the identification of dependencies in human–system interactions and computing their effects on performance failures. Spurgin (2010) discusses the use of the beta factor as a means for accounting for dependencies, where

$$P[\text{B}|\text{A}] = \beta P[\text{B}]$$

In this expression, $P[\text{B}|\text{A}]$ is the probability of B given that activity A has occurred, $P[\text{B}]$ is the probability of activity B independent of A, and $\beta$ is the dependency factor. One method for determining $\beta$ in HRA studies is by using an event tree (ET) to model the influence of dependencies in any particular sequence of human activities that might occur in an accident scenario. In such an ET, the columns would correspond to the various types of dependency variables that would be considered to impact activity B following activity A.

Examples of such dependency variables are cognitive connections between tasks, time available for actions to be taken, relationships among various crew members and support staff, and work stress due to workload. Each of these variables may have a number of discrete levels; for example, the time available variable may be classified as long, medium, and short, with the branch leading through a short amount of time resulting in a much larger beta factor. The various paths through *dependency ETs* would correspond to qualitatively different sets of dependency influences. Accordingly, the end branches of these paths would be designated by different beta values, with higher beta values resulting in increased HEPs associated with activity B.

The relationships between the levels of these input dependency variables and the designated end-branch dependence levels are, however, assumed to be based on expert judgment. To reduce the uncertainty associated with experts providing direct judgments on the dependence levels, a dependence assessment method based on fuzzy logic has been proposed (Podofillini et al., 2010). Using the same five levels of dependency as THERP, this approach assigns a number of different linguistic labels to dependency input variables (e.g., none, low, medium, high, very high) that can span ranges of values that can overlap with one another and, through an expert elicitation process, also provides anchor points to represent prototype conditions of the input variables for particular tasks. Judgments on these input variables can be given as point values on or between anchors or as

an interval range of values. These judgments are then assigned degrees of membership in fuzzy sets (based on trapezoidal membership functions), which represent the degrees to which the judgments match each of the linguistic labels. The expert's knowledge is represented as a set of rules by which the relationship between different values of the input variables and output (dependency level) variables is characterized. The fuzzy logic procedure used in this approach provides different degrees of activation of these rules and ultimately the degrees of belief in terms of the possibility for the different dependency levels (the output fuzzy set). For PRAs, a "defuzzification" procedure would be needed to convert this output set to probability values.

Generally, HRA analysts are free to select or modify whatever guidelines, such as those offered in Swain and Guttman (1983), and procedures to model dependencies. Handling dependencies remains, not unlike other aspects of HRA methods, as much art as science.

### 4.10.3  Deriving HEP Estimates

A fundamental issue that is troubling for many HRA methods, especially those that are based on assigning HEP values to tasks or elemental task activities, is the derivation of such HEP estimates. Ideally, HEP data should derive from the relevant operating experience or at least from similar industrial experiences. However, as Kirwan (1994) notes, there are a number of problems associated with collecting this type of quantitative HEP data. For example, many workers will be reluctant to report errors due to the threat of reprisals. Also, errors that do not lead to a violation of a company's technical specifications or that are recovered almost immediately will probably not be reported. In addition, data on errors associated with very low probability events, as in the execution of recovery procedures following an accident, may not be sufficiently available to produce reliable estimates and thus often require simulator studies for their generation.

Another problem is that error reports are usually confined to the observable manifestations of an error (the external error modes). Without knowledge of the underlying cognitive processes or psychological mechanisms, errors that are in fact dissimilar (Table 1) may be aggregated. This would not only corrupt the HEP data but could also compromise error reduction strategies.

Kirwan (1999) has reported on the construction of an HEP database in the United Kingdom referred to as CORE-DATA (computerized operator reliability and error database) for supporting HRA activities (in fact, as was noted in Section 4.4, the HRA method NARA relies on this database). While CORE-DATA currently contains a large number of HEPs, its long-term objective was to apply its data to new industrial contexts through the development of extrapolation rules. Other large-scale projects intended for obtaining HEP data in support of HRA are the human error repository and analysis project sponsored by the U.S. Nuclear Regulatory Commission (Halbert et al., 2006) for establishing empirical relationships between contextual factors and human performance failures and the International HRA Empirical Study that is being performed by a group of international organizations jointly with the Organisation for Economic Co-operation and Development Halden Reactor Project (Lois et al., 2008), in which simulator data are being used to validate the predictions of HRA methods (Boring et al., 2010).

In HRA, what seems undeniable is that much depends on the use of expert judgment, whether it is to identify relevant human interactions; provide a lower, nominal, or upper bound estimate of a human failure probability; identify contextual factors such as common performance conditions that could influence performance in a given scenario; generate importance weights and quality ratings for those factors; resolve the effects of dependencies among human activities and factors defining work contexts; or provide guidance on how to extrapolate human error data to new contexts. Ultimately, some form of expert judgment remains the underlying critical aspect governing all HRA methods.

## 5  MANAGING HUMAN ERROR

This Section is confined to a few select topics that have important implications for human error and its management. Specifically, this Section overviews some issues related to designer error, the role of automation in human error, human error in maintenance operations, and the use of incident-reporting systems.

### 5.1  Designer Error

Designer errors generally arise from two sources: inadequate or incorrect knowledge about the application area (i.e., a failure for designers to anticipate important scenarios) and the inability to anticipate how the product will influence user performance (i.e., insufficient understanding by designers). The vulnerability of designers to these sources of performance failure is not surprising when one considers that designers' conceptualizations typically are nothing more than initial hypotheses concerning the collaborative relationship between their technological products and human users. Accordingly, their beliefs regarding this relationship need to be gradually shaped by data that are based on actual human interaction with these technologies, including the transformations in work experiences that these interactions produce (Dekker, 2005).

Although designers have a reasonable number of choices available to them that can translate into different technical, social, and emotional experiences for users, like users they themselves are under the influence of sociocultural (Evan and Manion, 2002) and organizational factors. For example, the reward structure of the organization, an emphasis on rapid completion of projects, and the insulation of designers from the consequences of their design decisions can induce designers to give less consideration to factors related to ease of operation and even safety (Perrow, 1983).

According to Perrow (1999), a major deficiency in the design process is the inability of both designers and managers to appreciate human fallibility by failing to take into account relevant information that could be supplied by human factors and ergonomics specialists. While this concern is given serious consideration in

user-centered design practices (Nielsen, 1995), in some highly technical systems, where designers may still be viewing their products as closed systems governed by perfect logic, this issue may still exist.

### 5.1.1 User Adaptation to New Technologies

Much of our core human factors knowledge concerning human adaptation to new technology in complex systems has been derived from experiences in the nuclear power and aviation industries. These industries were forced to address the consequences of imposing on their workers major transformations in the way that system data were presented. In nuclear power control rooms, the banks of hardwired displays were replaced by one or a few computer-based display screens, and in cockpits the analog single-function single displays were replaced by sophisticated software-driven electronic integrated displays.

These changes drastically altered the human's visual–spatial landscape and offered a wide variety of schemes for representing, integrating, and customizing data. For those experienced operators who were used to having the entire "data world" available to them at a glance, the mental models and strategies that they had developed and relied on were not likely to be as successful when applied to these newly designed environments and perhaps even predisposed them to committing errors to a greater extent than their less experienced counterparts.

In complex work domains such as health care that require the human to cope with a potentially enormous number of different task contexts, anticipating the user's adaptation to new technology can become so difficult for designers that they themselves, like the practitioners who will use their products, can be expected to resort to the tendency to minimize cognitive effort (Section 2.2.5). Instead of designing systems with operational contexts in mind, one cognitively less taxing solution is to identify and make available all possible information that the user may require, but to place the burden on the user to search for, extract, or configure the information as the situation demands.

These designer strategies are often manifest as technological mediums that exhibit the *keyhole property*, whereby the size of the available "viewports" is very small relative to the number of data displays that potentially could be examined (Woods and Watts, 1997). Unfortunately, this approach to design makes it more likely that the user can "get lost in the large space of possibilities" and makes it difficult to find the right data at the right time as activities change and unfold.

An example of this problem was demonstrated in a study by Cook and Woods (1996) that examined adapting to new technology in the domain of cardiac anesthesia. In this study, physiological monitoring equipment dedicated to cardiothoracic surgery was upgraded to a computer system that integrated the functions of four devices onto a single display. By virtue of the keyhole property, the new technology created new interface management tasks to contend with that derived, in part, from the need to access highly interrelated data serially. New interface management tasks also included the need

to declutter displays periodically to avoid obscuring data channels that required monitoring. This requirement resulted from collapsing into a single device the data world that was previously made available through a multi-instrument configuration.

To cope with these potentially overloading situations, physicians were observed to tailor both the computer-based system (*system tailoring*) and their own cognitive strategies (*task tailoring*). For example, to tailor their tasks, they planned their interactions with the device to coincide with self-paced periods of low criticality and developed stereotypical routines to avoid getting lost in the complex menu structures rather than risk exploiting the system's flexibility. In the face of circumstances incompatible with task-tailoring strategies, the physicians had no choice but to confront the complexity of the device, thus diverting information-processing resources from the patient management function (Cook and Woods, 1996).

This *irony of automation*, whereby the burden of interacting with the technology tends to occur during those situations when the human can least afford to divert attentional resources, is also found in aviation. For example, automation in cockpits can potentially reduce workload by allowing complete flight paths to be programmed through keyboards. Changes in the flight path, however, require that pilots divert their attention to the numerous keystrokes that need to be input to the keyboard, and these changes tend to occur during takeoff or descent—the phases of flight containing the highest risk and that can least accommodate increases in pilot workload (Strauch, 2002).

Task tailoring reflects a fundamental human adaptive process. Thus, humans should be expected to shape new technology to bridge gaps in their knowledge of the technology and fulfill task demands. The concern with task tailoring is that it can create new cognitive burdens, especially when the human is most vulnerable to demands on attention, and mask the real effects of technology change in terms of its capability for providing new opportunities for human error (Dekker, 2005).

The provision of such new windows of opportunity for error was illustrated in a study by Cao and Taylor (2004) on the effects of introducing a remote robotic surgical system for laparoscopic surgery on communication among the operating room (OR) team members. In their study, communication was analyzed using a framework referred to as *common ground*, which represents a person's knowledge or assumptions about what other people in the communication setting know (Clark and Schaefer, 1989). The introduction of new technology into the OR provides numerous ways in which common ground, and thus patient safety, can become compromised. For example, roles may change, people become less familiar with their roles, the procedures for using the new technology are less familiar, and expectations for responses from communication partners become more uncertain. Misunderstandings can propagate through team members in unpredictable ways, ultimately leading to new forms of errors.

In this case, what these researchers found was that the physical barrier necessitated by the introduction of

the surgical robot had an unanticipated effect on the work context (Section 2.4). For example, the surgeon, now removed from the surgical site, had to rely almost exclusively on video images from this remote site. Consequently, instead of receiving a full range of sensory information from the visual, auditory, haptic, and olfactory senses, the surgeon had to contend with a "restricted field of view and limited depth information from a frequently poor vantage point" (Cao and Taylor, 2004, p. 310). These changes potentially overload the surgeon's visual system and also create more opportunities for decision-making errors due to gaps in the information that is being received (Section 2.2.3). Moreover, in addition to the need for obtaining information on patient status and the progress of the procedure, the surgeon has to cope with information-processing demands deriving from the need to access information about the status of the robotic manipulator. Ensuring effective coordination of the robotic surgical procedure actually entailed that the surgeon verbally distribute more information to the OR team members than with conventional laparoscopic surgery.

Overall, the communication patterns were found to be haphazard, which increased the team member's uncertainty concerning what information and when information should be distributed or requested. This has the potential for increasing human error resulting from miscommunication or lack of communication. Cao and Taylor suggested training to attain common ground, possibly through the use of rules or an information visualization system that could facilitate the development of a *shared mental model* among the team members (Stout et al., 1999).

## 5.2 Automation and Human Error

Innovations in technology will always occur and will bring with them new ways of performing tasks and doing work. Whether the technology completely eliminates the need for the human to perform a task or results in new ways of performing tasks through automation of selective task functions, the human's tasks will probably become reconfigured (Chapter 59). As demonstrated in the previous section, the human is especially vulnerable when adapting to new technology. During this period, knowledge concerning the technology and the impact it may have when integrated into task activities is relatively unsophisticated, and biases from previous work routines are still influential.

### 5.2.1 Levels of Automation

Automating tasks or system functions by replacing the human's sensing, planning, decision-making, or manual control activities with computer-based technology often requires making *allocation of function* decisions—that is, deciding which functions to assign to the human and which to delegate to automatic control (Sharit, 1997). Because these decisions can have an impact on the propensity for human error, the *level of automation* to be incorporated into the system needs to be carefully considered (Parasuraman et al., 2000; Kaber and Endsley,

2004). Higher levels of automation imply that automation will assume greater autonomy in decision making and control.

The primary concern with technology-centered systems is that they deprive themselves of the potential benefits that can be gained by virtue of the human being actively involved in system operations. These benefits can derive from the human's ability to anticipate, search for, and discern relevant data based on the current context; make generalizations and inferences based on past experience; and modify activities based on changing constraints. Determining the optimal level of automation, however, is a daunting task for the designer. While levels of automation somewhere between the lowest and highest levels may be the most effective way to exploit the combined capabilities of both the automation and the human, identifying an ideal level of automation is complicated by the need to also account for the consequences of human error and system failures (Moray et al., 2000).

In view of evidence that unreliable "decision automation" (e.g., automation that has provided imperfect advice) can more adversely impact human performance than unreliable "information automation" (e.g., automation that provides incorrect status information), it has been suggested, particularly in systems with high-risk potential, that the level of automation associated with decision automation be set to allow for human input into the decision-making process (Parasuraman and Wickens, 2008). This can be accomplished, for example, by allowing for the automation of information analysis (an activity that, like decision making, places demands on working memory) but allocating to the human the responsibility for the generation of the *values* associated with the different courses of action (Sections 2.2.1 and 2.2.3). The reduced vulnerability of human performance to unreliable information automation as compared to unreliable decision automation may lie in the fact that the "data world" (i.e., the raw input data) is still potentially available to the human under information automation.

### 5.2.2 Intent Errors in Use of Automation

In characterizing usage of automation, a distinction has been made between *appraisal errors* and *intent errors* (Beck et al, 2002) as a basis for *disuse* and *misuse* of automation (Parasuraman and Riley, 1997). Appraisal errors refer to errors that occur when the perceived utilities of the automated and nonautomated alternatives are inconsistent with the actual utilities of these options. In contrast, intent errors occur when the human intentionally chooses the option that lowers the likelihood of task success, despite knowledge of whether the automated or nonautomated alternative is more likely to produce the more favorable outcome. An intent error of particular interest is when humans refuse to use an automated device that they know would increase the likelihood of a successful outcome. For example, a human supervisory controller may choose to manually schedule a sequence of machining operations in place of using a scheduling aid that has proven utility for those decision-making scenarios.

One explanation for this type of intent error is the perception of the automation as a competitor or threat; this phenomenon is known as the *John Henry effect*. The hypothesis that personal investment in unaided (i.e., nonautomated) performance would increase the likelihood of the John Henry effect was tested by Beck et al. (2009) in an experimental study that manipulated both the participant's degree of personal investment and the reliability of the automated device in a target detection task. The findings supported the hypothesis that when the automation was more reliable than the human high personal investment would lead to its increased disuse, and when the automation was less reliable than the human it would lead to its lower misuse, relative to those participants with less personal involvement.

John Henry effects can be expressed in many ways. For example, an experienced worker who feels threatened by newly introduced automation may convince other co-workers not to use the device, in effect creating a recalcitrant work culture (Section 6). Some strategies for countering John Henry effects include demonstrating to workers the advantages of using the aid in particular scenarios and construing the automation as a partner or collaborator rather than as an adversary.

### 5.2.3 Automation and Loss of Skill

Well-designed automation can lead to a number of indirect benefits related to human performance. For example, automation in manufacturing operations that offloads the operator from many control tasks enables the human controller to focus on the generation of strategies for improving system performance. Reckless design strategies, however, that automate functions based solely on technical feasibility can often lead to a number of problems (Bainbridge, 1987). For instance, manual and cognitive skills that are no longer used due to the presence of automation will deteriorate, jeopardizing the system during times when human intervention is required. Situations requiring rapid diagnosis that rely on the human having available or being able to rapidly construct an appropriate mental model will thus impose higher working memory demands on humans who are no longer actively involved in system operations. The human may also need to allocate significant attention to monitoring the automation, which is a task humans do not perform well.

These problems are due largely to the capability for automation to insulate the human from the process and are best handled through training that emphasizes ample hands-on simulation exercises encompassing varied scenarios. The important lesson learned is that "disinvolvement can create more work rather than less, and produce a greater error potential" (Dekker, 2005, p. 165). This tenet was highlighted in a recent article concerning errors involving air traffic controllers and pilots that have led to a sudden increase in near collisions of airliners (*Wall Street Journal*, 2010). In some cases, pilots had to make last-second changes in direction following warnings by cockpit alarms of an impending crash. Although collision warning systems have, together with other advances in cockpit safety equipment, contributed to the decrease in major airline crashes over the last decade, as stated by U.S. Transportation Department Inspector General Mary Schiavo, one consequence of the availability of these systems, which essentially constitute a type of symbolic barrier system (Table 3), is that "it's easy for pilots to lose their edge." As was discussed in Section 2.4, the perception of these barrier systems by humans can alter the context in ways that can increase the human's predisposition for performance failures.

### 5.2.4 Mode Errors and Automation Surprises

Automation can be "clumsy" for the human to interact with, making it difficult to program, monitor, or verify, especially during periods of high workload. A possible consequence of clumsy automation is that it "tunes out small errors and creates opportunities for larger ones" (Weiner, 1985) by virtue of its complex connections to and control of important systems.

Automation has also been associated with *mode errors*, a type of mistake in which the human acts based on the assumption that the system is in a particular mode of operation (either because the available data support this premise or because the human instructed the system to adopt that mode), when in fact it is in a different mode. In these situations, unanticipated consequences may result if the system remains capable of accommodating the human's actions.

Generally, when the logic governing the automation is complex and not fully understood by the human, the actions taken by automatic systems may appear confusing. In these situations, the human's tendency for partial matching and biased assessments (Section 2.2) could lead to the use of an inappropriate rule for explaining the behavior of the system—a mistake that, in the face of properly functioning automation, could have adverse consequences. These forms of human–automation interaction have been examined in detail in flight deck operations in the cockpit and have been termed *automation surprises* (Woods et al., 1997).

Training that allows the human to explore the various functions of the automation under a wide range of system or device states can help reduce some of these problems. However, it is also essential that designers work with users of automation to ensure that the user is informed about what the automation is doing and the basis for why it is doing it. In the past, slips and mistakes by flight crews tended to be errors of commission. With automation, errors of omission have become more common, whereby problems are not perceived and corrective interventions are not made in a timely fashion.

### 5.2.5 Mistrust of and Overreliance on Automation

When the performance of automatic systems or subsystems is perceived to be unreliable or uncertain, *mistrust of automation* can develop (Lee and Moray, 1994; Rasmussen et al., 1994). As Lee and See (2004) have pointed out, many parallels exist between the trust that we gain in other people and the trust we acquire in complex technology, and as in our interactions with other people, we tend to rely on automation we trust and reject automation we do not trust.

Mistrust of automation can provide new opportunities for errors, as when the human decides to assume manual control of a system or decision-making responsibilities that may be ill-advised under the prevailing conditions. Mistrust of automation can also lead to its disuse, which impedes the development of knowledge concerning the system's capabilities and thus further increases the tendency for mistrust and human error. To help promote appropriate trust in automation, Lee and See suggest that the algorithms governing the automation be made more transparent to the user; that the interface provide information regarding the capabilities of the automation in a format that is easily understandable; and that training address the varieties of situations that can affect the capabilities of the automation.

Harboring high trust in imperfect automation could also lead to human performance failures as a result of the *complacency* that could arise from *overreliance on automation*. A particularly dangerous situation is when the automation encounters inputs or situations unanticipated in its design but which the human believes the automation was programmed to handle.

In situations involving monitoring information sources for critical state changes, overreliance on the automation to perform these functions could lead to the human diverting resources of attention to other concurrent tasks. One way to counter such overreliance on automation is through *adaptive automation* (Sharit, 1997; Parasuraman and Wickens, 2008), which returns the automated task to human control when the (adaptive) automated system detects phases when human workload is low. Such a reallocation strategy, when implemented sporadically, could also serve to refresh and thus reinforce the human's mental model of automated task behavior.

System-driven adaptation, however, whether it is initiated for the purpose of countering complacency during low-workload phases or for off-loading the human during high-workload phases, adds an element of unpredictability to the overall human–system interactive process. The alternative solution of shifting the control of the adaptive process to the human may, on the other hand, impose an excessive decision-making load. Not surprisingly, implementing effective adaptive automation designs in complex work domains remains a challenging area.

### 5.3   Human Error in Maintenance

To function effectively, almost all systems require maintenance. Frequent scheduled (i.e., preventive) maintenance, however, can be costly, and organizations often seek to balance these costs against the risks of equipment failures. Lost in this equation, however, is a possible "irony of maintenance"—an increased frequency in scheduled maintenance may actually increase system risk by providing more opportunities for human interaction with the system (Reason, 1997). This increase in risk is more likely if assembly rather than disassembly operations are called for, as the comparatively fewer constraints associated with assembly operations make these activities much more susceptible to various errors,

such as identifying the wrong component, applying inappropriate force, or omitting an assembly step (Lehto and Buck, 2008).

Maintenance environments are notorious for breakdowns in communication, often in the form of implicit assumptions or ambiguity in instructions that go unconfirmed (Reason and Hobbs, 2003). When operations extend over shifts and involve unfamiliar people, these breakdowns in communication can propagate into catastrophic accidents, as was the case in the explosion aboard the Piper Alpha oil and gas platform in the North Sea (Reason and Hobbs, 2003) and the crash of ValueJet flight 592 (Strauch, 2002).

Incoming shift workers are particularly vulnerable to errors following the commencement of their task activities, especially if maintenance personnel in the outgoing shift fail to brief incoming shift workers adequately concerning the operational context about to be confronted (Sharit, 1998). In these cases, incoming shift workers may be placed in the difficult position of needing to invest considerable attention almost immediately in order to avoid an incident or accident.

Many preventive maintenance activities initially involve searching for flaws prior to applying corrective procedures, and these search processes are often subject to various expectancies that could lead to errors. For example, if faults or flaws are seldom encountered, the likelihood of missing such targets will increase; if they are encountered frequently, properly functioning equipment may be disassembled. Maintenance workers are also often required to work in restricted spaces that are error inducing by virtue of the physical and cognitive constraints that these work conditions can impose (Reynolds-Mozrall et al., 2000).

Flawed partnerships between maintenance workers and troubleshooting equipment can also give rise to errors. As with other types of aiding devices, troubleshooting aids can compensate for human limitations and extend human capabilities when designed appropriately. However, these devices are often opaque and may be misused or disregarded (Parasuraman and Riley, 1997). For instance, if the logic underlying the software of an expert troubleshooting system is inaccessible, the user may not trust the recommendations or explanations given by the device (Section 5.2) and therefore choose not to replace a component that the device has identified as faulty.

Errors resulting from interruptions are particularly prevalent in maintenance environments. Interruptions due to the need to assist a co-worker or following the discovery that the work procedure called for the wrong tool or equipment generally require the worker to leave the scene of operations. In these kinds of situations, the most likely type of error is an omission. In fact, memory lapses probably constitute the most common errors in maintenance, suggesting the need for incorporating good reminders (Reason, 1997). Reason and Hobbs (2003) emphasize the need for mental readiness and mental rehearsal as ways that maintenance workers can inoculate themselves against errors that could arise from interruptions, time pressure, communication, and unfamiliar situations that may arise.

Written work procedures are pervasive in maintenance operations, and numerous problems with the design of these procedures may exist that can predispose their users to errors (Drury, 1998). Violations of these procedures are also relatively common, and management has been known to consider such violations as causes and contributors of adverse events. This belief, however, is both simplistic and unrealistic, and may be partly due to the fact that work procedures are generally based on normative models of work operations. The actual contexts under which real work takes place are often very different from those that the designers of the procedures have envisioned or were willing to acknowledge. To the followers of the procedures, who must negotiate their tasks while being subjected to limited resources, conflicting goals, and pressures from various sources, the cognitive process of transforming procedures into actions is likely to expose incomplete and ambiguous specifications that, at best, appear only loosely related to the actual circumstances (Dekker, 2005).

A worker's ability to adapt (and thereby violate) these procedures successfully may, in fact, be lauded by management and garner respect from fellow workers. However, if these violations happen to become linked to accidents, management would most likely refute their knowledge or tacit approval of these informal activities and retreat steadfastly to the official doctrine—that safety will be compromised if workers do not follow procedures. Dekker suggests that organizations monitor (Section 5.4) and understand the basis for the gaps between procedures and practice and develop ways of supporting the cognitive skill of applying procedures successfully across different situations by enhancing workers' judgments of when and how to adapt.

## 5.4 Incident-Reporting Systems

Information systems such as incident-reporting systems (IRSs) can allow extensive data to be collected on incidents, accidents, and human errors. *Incidents* comprise events that are not often easy to define. They may include actions, including human errors, responsible for the creation of hazardous conditions. They may also include *near misses*, which are sometimes referred to as close calls.

Capturing information on near misses is particularly advantageous as, depending on the work domain, near misses may occur hundreds of times more often than adverse events. The contexts surrounding near misses, however, should be similar to and thus highly predictive of accidents. The reporting of near misses, especially in the form of short event descriptions or detailed anecdotal reports, could then provide a potentially rich set of data that could be used as a basis for proactive interventions.

The role of management is critical to the successful development and implementation of an IRS (CCPS, 1994). Management not only allocates the resources for developing and maintaining the system but can also influence the formation of work cultures that may be resistive to the deployment of IRSs. In particular, organizations that have instituted "blame cultures" (Reason, 1997) are unlikely to advocate IRSs that emphasize underlying causes of errors, and workers in

these organizations are unlikely to volunteer information to these systems.

Often, the data that is collected or its interpretation will reflect management's attitudes concerning human error causation. The adoption of a system-based perspective on human error would imply the need for an information system that emphasizes the collection of data on possible causal factors, including organizational and management policies responsible for creating the latent conditions for errors. A system-based perspective on human error is also conducive to a dynamic approach to data collection: If the methodology is proving inadequate in accounting for or anticipating human error, it will probably be modified.

Worker acceptance of an IRS that relies on voluntary reporting entails that the organization meet three requirements: exact a minimal use of blame; ensure freedom from the threat of reprisals; and provide feedback indicating that the system is being used to affect positive changes that can benefit all stakeholders. Accordingly, workers would probably not report the occurrence of accidental damage to an unforgiving management and would discontinue voluntarily offering information on near misses if insights gained from intervention strategies are not shared (CCPS, 1994). It is therefore essential that reporters of information perceive IRSs as error management or learning tools and not as disciplinary instruments.

In addition to these fundamental requirements, two other issues need to be considered. First, consistent with user-centered design principles (Nielsen, 1995), potential users of the system should be involved in its design and implementation. Second, effective training is critical to the system's usefulness and usability. When human errors, near misses, or incidents occur, the people who are responsible for their reporting and investigation need to be capable of addressing in detail all considerations related to human fallibility, context, and barriers that affect the incident. Thus, training may be required for recognizing that an incident has in fact occurred and for providing full descriptions of the event.

Analysts also would need training, specifically, on applying the system's tools, including the use of any modeling frameworks for analyzing causality of human error, and on interpreting the results of these application tools. They would also need training on generating summary reports and recommendations and on making modifications to the system's database and inferential tools if the input data imply the need for such adjustments.

Data for input into IRSs can be of two types: quantitative data, which are more readily coded and classified, and qualitative data in the form of free-text descriptions. Kjellén (2000) has specified the basic requirements for a safety information system in terms of data collection, distribution and presentation of information, and overall information system attributes. To meet data collection requirements, the input data need to be reliable (i.e., if the analysis were to be repeated, it should produce similar results) and accurate and provide adequate coverage (e.g., on organizational and human factors issues) needed for exercising efficient control.

Foremost in the distribution and presentation of information is the need for *relevant* information. Relevance will depend on how the system will be used. For example, if the objective is to analyze statistics on accidents in order to assess trends, a limited set of data on each accident or near miss would be sufficient and the nature of these data can often be specified in advance. However, suppose that the user is interested in querying the system regarding the degree to which new technology and communication issues have been joint factors in incidents involving errors of omission. In this case, the relevance will be decided by the coverage. Generally, the inability to derive satisfactory answers to specific questions will signal the need for modifications of the system.

### 5.4.1 Aviation Safety Reporting System

The Aviation Safety Reporting System (ASRS) was developed in 1976 by the Federal Aviation Administration (FAA) in conjunction with NASA. Many significant improvements in aviation practices have since been attributed to the ASRS, and these improvements have largely accounted for the promotion and development of IRSs in other work domains, most notably, the health care industry, which has been struggling with what has been termed an epidemic of adverse events stemming from medical errors (Kohn et al., 1999).

The ASRS's mission is threefold: to identify deficiencies and discrepancies in the National Aviation System (NAS); to support policy formulation and planning for the NAS; and to collect human performance data and strengthen research in the aviation domain. All pilots, air traffic controllers, flight attendants, mechanics, ground personnel, and other personnel associated with aviation operations can submit confidential reports if they have been involved in or observed any incident or situation that could have a potential effect on aviation safety. The ASRS database can be queried by accessing its Internet site (http://asrs.arc.nasa.gov).

ASRS reports are processed in two stages by groups of analysts composed of experienced pilots and air traffic controllers. In the first stage, each report is read by at least two analysts who identify incidents and situations requiring immediate attention. Alerting messages are then drafted and sent to the appropriate group. In the second stage, analysts classify the reports and assess causes of the incident. Their analyses and the information contained in the reports are then incorporated into the ASRS database. The database consists of the narratives submitted by each reporter and coded information that is used for information retrieval and statistical analysis procedures.

Several provisions exist for disseminating ASRS outputs. These include alerting messages that are sent out in response to immediate and hazardous situations; the *CALLBACK* safety bulletin, which is a monthly publication containing excerpts of incident report narratives and added comments; and the ASRS *Directline*, which is published to meet the needs of airline operators and flight crews. In addition, in response to database search requests, ASRS staff communicates with the FAA and the National Transportation Safety Board (NTSB) on

an institutional level in support of various tasks, such as accident investigations, and conducts and publishes research related primarily to human performance issues.

### 5.4.2 Some Issues with IRSs

Some IRSs, by virtue of their inability to cope with the vast number of incidents in their databases, have apparently become "victims of their own success" (Johnson, 2002). The FAA's ASRS and the Food and Drug Administration's MedWatch Reporting System (designed to gather data on regulated, marketed medical products, including prescription drugs, specialized nutritional products, and medical devices) both contain enormous numbers of incidents. Because their database technologies were not designed to manage this magnitude of data, users who query these systems are having trouble extracting useful information and often fail to identify important cases.

This is particularly true of the many IRSs that rely on *relational database* technology. In these systems, each incident is stored as a record, and incident identifiers are used to link similar records in response to user queries. Relational database techniques, however, do not adapt well to changes in either the nature of incident reporting or the models of incident causation.

Another concern is that different organizations in the same industry tend to classify events differently, which reduces the benefits of drawing on the experiences of IRSs across different organizations. It can also be extremely difficult for people who were not involved in the coding and classification process to develop appropriate queries (Johnson, 2002).

Problems with IRSs can also arise when large numbers of reports on minor incidents are stored. These database systems may then begin to drift toward reporting information on quasi-incidents and precursors of quasi-incidents, which may not necessarily provide the IRS with increased predictive capability. As stated by Amalberti (2001), " The result is a bloated and costly reporting system with not necessarily better predictability, but where everything can be found; this system is chronically diverted from its true calling (safety) to serve literary or technical causes. When a specific point needs to be proved, it is (always) possible to find confirming elements in these extra-large databases" (p. 113).

A much more fundamental problem with IRSs is the difficulty in assuring anonymity to reporters of information, especially in smaller organizations. Although most IRSs are confidential, anonymity is more conducive to obtaining disclosures of incidents. Unfortunately, anonymity precludes the possibility for follow-up interviews, which are often necessary for clarifying reported information (Reason, 1997).

Being able to follow up interviews, however, does not always resolve problems contained in reports. Gaps in time between the submission of a report and the elicitation of additional contextual information can result in important details being forgotten or confused, especially if one considers the many forms of bias that can affect eyewitness testimony (Johnson, 2002). Biases that can affect reporters of incidents can also affect the teams of people (i.e., analysts) that large-scale IRSs often employ

to analyze and classify the reports. For example, there is evidence that persons who have received previous training in human factors are more likely to diagnose human factors issues in incident reports than persons who have not received this type of training (Lekberg, 1997).

IRSs that employ classification schemes for incidents that are based on detailed taxonomies can also generate confusion, and thus variability, among analysts. Difficulty in discriminating between the various terms in the taxonomy may result in low recall systems, whereby some analysts fail to identify potentially similar incidents. Generally, limitations in analysts' abilities to interpret causal events reduce the capability for organizations to draw important conclusions from incidents, whereas analyst bias can lead to organizations using IRSs for supporting existing preconceptions concerning human error and safety.

The FAA's Aviation Safety Action Program (ASAP), a voluntary carrier-specific safety program that grew out of the success of the FAA's ASRS (Section 5.4.1), exemplifies the challenges in developing a classification scheme capable of identifying underlying causes of errors. In this program, pilots can submit short text descriptions of incidents that occurred during line operations. Although extracting diagnostic information from ASAP's text narratives can be an arduous task, it could be greatly facilitated if pilots were able to classify causal contributors of incidents when filing these reports. Baker and Krokos (2007) detail the development of such a classification system, referred to as ACCERS (Aviation Causal Contributors for Event Reporting Systems), in a series of studies involving pilots who were used to both establish as well as validate this system's taxonomic structure. An initial set of about 300 causal contributors were ultimately transformed into a hierarchical taxonomy consisting of seven causal categories (e.g., policies or procedures, human error, human factors, and organizational factors) and 73 causal factors that were assigned to one of these seven categories (e.g., conflicting policies and procedures, misapplication of flight controls, proficiency/overreliance on automation, and airline's safety culture).

Despite results which suggested that ACCERS reasonably satisfied three important evaluation criteria in taxonomy development—internal validity, external validity, and perceived usefulness—a number of problems existed that highlight the confusion that taxonomies can bring about. For example, pilots had difficulty differentiating between the human error and human factors categories, possibly due to confounding the error "outcome" with the "performance itself." Also, interrater agreement was relatively low, especially at the factor level (i.e., selecting factor-level causal contributors to the incident in the ASAP report), suggesting the need for training to ensure greater consistency in appraising the meaning of the causal factors.

Issues associated with error or incident reporting can also be highly work-domain specific. For example, the presumed considerable underreporting of medical incidents and accidents in the health care industry is likely to be due to a number of relatively unique barriers to reporting that this industry faces (Holden and Karsh,

2007). One issue is that many medical providers, by virtue of the nature of their work, may not be willing to invest the effort in documenting incidents or filing reports. Even electronic IRSs that may make it seem relatively easy to document errors or incidents (e.g., through drop-down menus) may still demand that the reporter collect or otherwise track down supportive information, which may require leaving one's work area at the risk of a patient's safety.

Many medical providers may not even be aware of the existence of a medical IRS. For example, they may not have been present when these systems were introduced or when training on them was given or were somehow not informed of their existence. The existence or persistence of any of these kinds of situations is symptomatic of managerial failure to provide adequate commitment to the reporting system. Another consideration is the transient nature of many complex medical environments. For example, some medical residents or part-time nurses, for reasons related to fear or distrust of physicians in higher positions of authority or because they do not perceive themselves as stakeholders in the organization, may not feel as compelled to file incident reports. Many medical providers, including nurses and technicians, may not even have an understanding of what constitutes an "error" or "incident" and may require training to educate them on the wide range of situations that should be reported and, depending on the IRS, how these situations should be classified. More generally, blame cultures are likely to be more prevalent in medical environments, where a fear of reprimand, being held liable, or the stigma associated with admissions of negligence or fallibility (Holden and Karsh, 2007) is still well established in many workers. In fact, in some electronic IRSs the wording of the disclaimer regarding the nature of protection the reporting system provides the worker may be sufficient reason for some workers not to use the system.

Finally, a very different type of concern arises when IRSs are used as a basis for quantitative human error applications. In these situations, the voluntary nature of the reporting may invalidate the data that are used for deriving estimates of human error probabilities (Thomas and Helmreich, 2002). From a probabilistic risk assessment (Section 4) and risk management perspective, this issue can undermine decisions regarding allocating resources for resolving human errors: Which errors do you attempt to remediate if it is unclear how often the errors are occurring?

### 5.4.3 Establishing Resiliency through IRSs

A kind of information that would be advantageous to catalog but that is extremely challenging to capture by the current state-of-the-art in incident reporting concerns the various adaptations by an organization's constituents to the external pressures and conflicting goals to which they are continuously subjected (Dekker, 2005). Instead of the more salient events that signal reporting in conventional IRSs, these adaptations, as might occur when a worker confronts increasingly scarce resources while under pressure to meet higher production standards,

can give rise to potentially risky conditions—a process that can be characterized as *drifting into failure*.

If the adaptive responses by the worker to these demands gradually become absorbed into the organization's definition of normal work operations, work contexts that may be linked to system failures are unlikely to be reported and thus remain concealed. The intricate, incremental, and transparent nature of the adaptive processes underlying these drifts may be manifest at various levels of an organization. Left unchecked, the aggregation of these drifts seals an organization's fate by effectively excluding the possibility for proactive risk management solutions. In the case of the accident in Bhopal (Casey, 1993), these drifts were personified at all levels of the responsible organization.

Although reporting systems such as IRSs can, in theory, monitor and detect these types of drifts into failure, to do so these systems may need to be driven by new models of organizational dynamics and armed with new levels of intelligence. Overall, devising, managing, and effectively utilizing a reporting system capable of capturing an organization's adaptive capacity relative to the dynamic challenges to that capacity is consistent with the goal of creating a *resilient organization* (Dekker, 2005, 2006).

Presently, however, we have few models or frameworks to guide this process. To establish resiliency, this type of reporting enterprise would need to be capable of identifying the kinds of disruptions to its goals that can be absorbed without fundamental breakdowns in its performance or structure; when and how closely the system appears to be operating near its performance boundary; details related to the behavior of the system when it nears such a boundary; the types of organizational contexts, including management policies, that can resolve various challenges to system stability such as dealing with changing priorities, allocating responsibility to automation, or pressure to trade off production with safety concerns; and how adaptive responses by workers to these challenges, in turn, influence management policies and strategies (Woods, 2006). Getting the relevant data underlying these issues, let alone determining how this data should be exploited, remains a challenging problem.

Finally, while the focus in safety has largely been on models of failure, reflecting attempts to "confirm" our theories about how human error and failure events can result in accidents, in contrast we have little understanding of how normal work leads to stable system performance. This knowledge is prerequisite for determining how drifts become established and the kinds of system instability they can produce, especially when such drifts are built on a succession of incremental departures from previously established norms.

Identifying such drifts is further complicated by the reality that such incremental departures by one or more workers in response to system demands may produce simultaneous adaptive incremental responses by many other system constituents, including suppliers, managers, and even regulators, which can mask the initial behavioral departures. Collectively, these challenges are encapsulated by Dekker (2006) as follows: "a true model of drift may be out of reach altogether since it may be fundamentally immeasurable" (p. 85).

## 6  ORGANIZATIONAL CULTURE AND RESILIENCE

There are numerous factors with regard to the culture of an organization that are relevant to the topics of human error, risk, and safety. For example, Strauch (2002) identified two factors that he considered cultural antecedents to erroneous performance in organizations: identification with the group and acceptance of authority. In Hofstede's (1991) analysis of the influence of company cultures on behaviors among individuals, these factors were termed *individualism–collectivism* (the extent to which people identify with the group) and *power distance* (the extent to which people accept authority).

Whereas individually oriented people place personal goals ahead of organizational goals, collectivist-oriented persons tend to identify with the company (or work group), so that more of the responsibility for errors that they commit would be deflected onto the company. These distinctions thus may underlie attitudes that could affect the degree to which workers mentally prepare themselves for potential errors.

*Power distance* refers to the differences in power that employees perceive between themselves and subordinates and superiors. In cultures with high power distance, subordinates are less likely to point out or comment to others about errors committed by superiors as compared to workers in company cultures with low power distance. Cultures in which workers tend to defer to authority can also suppress the organization's capability for learning. For example, workers may be less willing to make suggestions that can improve training programs or operational procedures (Section 5.4).

Hofstede identified a third cultural factor, called *uncertainty avoidance*, which refers to the willingness or ability to deal with uncertainty; this factor also has implications for human error. For example, workers in cultures that are low in uncertainty avoidance are probably more likely to invoke performance at the knowledge-based level (Section 2.2.4) in response to novel or unanticipated situations for which rules are not available.

Another distinction related to organizational culture, especially in reference to industries engaged in high-risk operations, is whether an organization can be considered a *high-reliability organization* (HRO). Attributes generally associated with HROs include anticipating errors and encouraging safety at the expense of production; having effective error-reporting mechanisms without fear of reprisals; and maintaining channels of communication across all levels of the company's operations (Rochlin et al., 1987; Roberts, 1990; Bierly and Spender, 1995; Weick et al., 1999). In contrast, questionable hiring practices, poor economic incentives, inflexible and outmoded training programs, the absence of IRSs and meaningful accident investigation mechanisms, managerial instability, and the promotion of atmospheres that

discourage communication between superiors and subordinates represent attributes reflective of poor organizational cultures.

Through policies that prescribe a proactive safety culture, the mindset of HROs makes it possible to avert many basic human and system performance failures that plague numerous organizations. For example, HROs typically have policies in place that serve to ensure that various groups of workers interface with one another; relevant information, tools, and other specialized resources are available when needed; and problems do not arise due to inadequate staffing.

It can be argued that the attributes that often define an HRO also promote resiliency (Section 5.4.3). Organizations with "fortress mentalities" that lack a "culture of conscious inquiry" are antithetical to HROs; such organizations are more likely to miss potential risks that are unfolding and less likely to identify critical information needed to cope with the complexity that these situations carry (Westrum, 2006).

Building on work by Reason (1997) and Reason et al. (1998), Wreathall (2006) has identified the following seven organizational cultural themes which characterize the processes by which organizations become resilient in terms of both safety and production:

- *Top-Level Commitment*. Top-level management is attuned to human performance concerns and provides continuous and extensive follow-through to actions that address these concerns.
- *Just Culture*. As emphasized in Section 5.4, the perceived absence of a just culture will lessen the willingness of workers to report problems, ultimately diminishing the effectiveness of proactive risk management strategies.
- *Learning Culture*. Section 5.4 also alluded to the importance of well-designed and well-managed IRSs as a basis for enabling an organization to learn. However, this theme also encompasses the need to shed or otherwise avoid cultural attributes that can suppress organizational learning. An example of such an attribute is what Cook and Woods (2006) refer to as "distancing through differencing," whereby an organization may discount or distance itself from incidents or accidents that occur in other organizations with similar operations through various rationalizations that impede the possibility for learning.
- *Awareness*. This theme emphasizes the ongoing ability to extract insights from data gathered through reporting systems that can be used to gauge and rethink risk management models.
- *Preparedness*. This theme reflects a mindset of an organization that is continually anticipating mechanisms of failure (including human performance failures) and problems (including how improvements and other changes might induce new paths to failure), even when there has not been a recent history of accidents, and prepares for these potential problems (e.g., by ensuring the availability of needed resources for serious anomalous events).

- *Flexibility*. Organizations that embrace a learning culture are more likely to accord their supervisors with the flexibility to make adaptive responses in the face of routine and major crises that involve making difficult trade-off decisions.
- *Opacity*. The "open" culture that characterizes HROs, which allows interactions of individuals at all levels and encourages cross-monitoring and the open articulation of safety concerns without reprisals, provides such organizations with the buffering capacity to move toward safety boundaries without jeopardizing the safety or productivity of its operations.

To these themes one should add the willingness of management to temporarily relax the efficiency goal for the safety goal when circumstances dictate the need for doing so (Sheridan, 2008). Such circumstances appeared to be apparent in the case of the Deepwater Horizon accident (Section 6.2).

In Section 2.2.5, a number of common rules people apply were offered to exemplify the manifestation of the concept of the efficiency–thoroughness trade-off (ETTO) proposed by Hollnagel (2004). The manifestation of ETTO rules at the organizational level provides yet another basis upon which company cultures can be distinguished in terms of their propensity for inducing performance failures. Hollnagel (2004) offers the following examples of ETTO rules at the level of the organization:

- *Negative Reporting*. This rule drives organizations to report only deviations from normal states; the organization's "cognitive effort" is minimized by interpreting a lack of information as a confirmation that everything is safe.
- *Reduction of Uncertainty*. Overall physical and cognitive resources are saved through elimination of independent checks.
- *Management Double Standards*. This is personified in the classic situation whereby efficiency, in the form of meeting deadlines and productivity, is "pushed," often tacitly, on its workers, at the expense of the thoroughness that would be needed to ensure the safety standards that the organization purportedly, in its official doctrine, covets.

Another telltale sign that an organization's culture may be lacking in resilience, especially in its ability to balance the pressures of production with concerns for safety, resides in the nature of its maintenance operations. This was apparent in the crash of ValueJet flight 592 into the Florida Everglades in 1996 just minutes after takeoff. The crash occurred following an intense fire in the airplane's cargo compartment that made its way into the cabin and overcame the crew (Strauch, 2002). Unexpended and unprotected canisters of oxygen generators, which can inadvertently generate oxygen and heat and consequently ignite adjacent materials, had somehow managed to become placed onto the aircraft.

Although most of the errors that were uncovered by the investigation were associated with maintenance technicians at SabreTech—the maintenance facility contracted by ValueJet to overhaul several of its aircraft—these errors were attributed to practices at SabreTech that reflected organizational failures. For example, although the work cards (which specified the required steps for performing maintenance tasks) indicated either disabling the canisters with locking caps or expending them, these procedures were not carried out. Contributing to the failure to carry out these procedures was the unavailability of the locking caps needed to secure the unexpended oxygen generators. In addition, maintenance workers incorrectly tagged the canisters. Instead of applying red tags, which would have correctly identified the removed canisters as condemned or rejected components (the canisters were in fact expired), they applied green tags, which signified the need for further repairs or testing. Workers in shipping and receiving, who were ultimately responsible for placing the canisters on the airplane, thus assumed the canisters were to be retained. Had the correctly colored tags been attached to the components, these personnel would likely have realized that the canisters were of no value and thus were not to be returned to the airline.

There was also a lack of communication across shifts concerning the hazards associated with the oxygen generators, which was facilitated by the absence of procedures for briefing incoming and outgoing shift workers concerning hazardous materials and for tracking tasks performed during shifts. Deficiencies in training were also cited as a contributory cause of the accident. Although SabreTech provided instruction on various policies and procedures (e.g., involving inspection and hazardous material handling), contractor personnel, who comprised the majority of the company's technicians who worked on the canisters, received no training.
